Cisternal and Spinal Punctures in Mental Disturbances.—To determine whether the examination of the fluid obtained by cisternal puncture gives as valuable diagnostic information as that obtained by spinal puncture, Kulcsar compared the data on the two punctures from 150 patients. He is convinced that in normal cases the differences in the two specimens manifest themselves only in a somewhat higher sugar value of the cisternal fluid and a slightly greater cell count of the spinal (lumbar) fluid. In disorders of the central nervous system the differences are greater and generally show a higher number of cells and a higher globulin content of the spinal fluid while in the cisternal fluid the Wassermann reaction and the colloidal reactions show a lesser positivity. If this is taken into consideration the observations on the cisternal fluid will permit conclusions about the changes in the fluid obtained by spinal puncture and even slight changes in the cisternal fluid can be considered pathologic. In most cases the examination of the cisternal fluid gives just as valuable information as that of the spinal fluid. But it is natural that the fluid which is withdrawn from the region of the pathologic focus shows the severest changes. In disorders of the spinal cord or of the roots, it is logical for the spinal puncture to be done in addition to the cisternal puncture. In nervous and mental disturbances however the cisternal puncture should be made first because there is hardly any meningism following it, and the result of the examination of this specimen gives about as much information as does that of the spinal specimen. The spinal puncture should be made only if certain conditions make it necessary.

Hereditary Anonychia and Onychatrophy.—Kemp and Andersen say that these conditions occur partly as isolated malformations partly with other abnormalities particularly patellar defect, other bone and joint malformations and hand dystrophy. In the family described nineteen out of thirty three members in six generations had anonychia or onychatrophy, inherited as a dominant monomeric characteristic. No other hereditary anomalies appeared in the family.

SUPPURATIONS OF THE PETROUS TIP

EDMUND P FOWLER JR, MD

NEW YORK

The symptoms and signs, the essential pathologic changes and the treatment of simple mastoiditis are known to physicians throughout the world. In the few years, otologic journals have contained many reports of a similar but somewhat more obscure disease of the temporal bone, namely, petrositis or inflammation of the petrosal portion of the bone. During the four years that routine serial sections of the temporal bones have been done in the Department of Pathology of the Stryker Hospital, six cases of meningitis of otic origin have been sectioned out of 1,165 general autopsies.

All these patients had petrositis.¹ Four of the improved cases were from the medical wards and two in the ear service. This suggests that the disease might be of considerable interest to the general medical

suppurations of the temporal bone other than those of the middle ear, mastoid and zygoma have been recognized more and more since 1904, when Gradenigo² first described a syndrome of external rectus paralysis and terminal pain associated with a discharging ear. He placed particular stress on the external rectus paralysis, which he ascribed to disease of the bone in the neighborhood of Dorello's canal, in which runs the abducens nerve. In other words, he described a type of posterior petrositis. Many writers since Gradenigo have shown that unilateral trigeminal pain is perhaps the most important symptom of petrositis, because sixth nerve paralysis can be caused by many other conditions.³ But the most characteristic pain, which is behind the eye, can also be produced by cavernous, petrosal or sigmoid sinus thrombosis, by brain tumor or brain abscess of tasteless origin, as well as by a simple toxic neuritis of the fifth nerve from a distant focus so that these must be considered in the differential diagnosis of the disease.

Recently Kopetzky and Almour⁴ have written a monograph on petrositis in which they survey the literature and clarify the subject. They have furthermore devised an operation to drain the petrous tip even pass a dental drill between the cochlea and the otoid canal or above them and so afford an outlet

for the pus in the bone beyond. Eagleton⁴ has also developed an operation for draining the tip and the basilar meningitis, which often occurs when a suppurative process breaks through the cortex of the tip. He makes a large decompression based on the approach to the gasserian ganglion operation for tic douloureux and then skeletonizes the temporal bone posteriorly if there is a meningitis present.

In a study of this subject it is important to remember that not only the mastoid and zygomatic portions of the temporal bone may be pneumatized. Kopetzky and Almour estimate that about one third of all temporal bones show some air cells in the petrous tip. It has been shown by Wittmaack⁵ that the air cells in the mastoid are developed by invagination of epithelial elements from the middle ear. The cells in the petrosa are developed by a similar invagination. The air cells communicate with one another and, more important still, they communicate with the middle ear, so that if there is an inflammatory process in the middle ear there is usually more or less inflammatory reaction in the mastoid and the petrous cells. That is, with every otitis media there is always more or less mastoiditis, and if there are cells in the petrosa, always more or less petrositis. The more pneumatized the petrosa the more likely is involvement of this portion of the bone, but occasionally, as will be described later, there is disease present even when the spaces between the bone trabeculae are entirely filled with marrow.

The diagnosis of petrositis is not as easy as that of simple mastoiditis, a series of histories, however, shows that there is a more or less typical disease picture.

REPORT OF CASES

CASE 1—A Negro, aged 37, a music teacher, had a mild ache in the left ear four weeks before his admission to the hospital. Two weeks before admission a left sided frontal and parietal headache developed for which he consulted a physician. The latter treated him for sinusitis without relief. The day before admission the patient had quite a severe headache, but he managed to work all day. That evening he began to vomit and then quickly became delirious. He was admitted next morning to the medical wards in a coma with a temperature of 106.5 F and all the classic symptoms and signs of meningitis. There was slight bulging of the left drum, but no pus appeared after myringotomy. Examination of the throat, chest and abdomen was entirely negative. The spinal fluid contained 130,000 cells per cubic millimeter, with 89 per cent polymorphonuclear neutrophils and pneumococcus type III. Culture of the blood was negative. He died in the evening, twenty-four hours after first going into coma.

Roentgenograms in the mentovertical position taken after death show a definite washing out of the cells of the tip on

From the Department of Pathology, Columbia University College of Physicians and Surgeons, under funds from the Department of Otolaryngology, the New York League for the Hard of Hearing and the American Otological Society.

¹ Head permission is granted in only one third of the cases and in less than two suspected cases microscopic preparations have not as yet been made.

the left side (fig 1). There is some thickening of the cell walls on both sides suggestive of a chronic disease of long standing or repeated attacks of otitis. Curiously enough, however, when the temporal bones were removed there was very little gross difference between the two sides. Perhaps the left petrous tip was a bit more succulent, but several observers were unable to be sure of any disease in either side. However, microscopically there is a vast difference. The temporal bones are of the pneumatic type (fig 2). On one side the cells are filled with a purulent exudate consisting of large mononuclear cells and occasional polymorphonuclear neutrophils (fig 3). The cell walls are thick and in many places there is a regrowth of pink staining bone as well as areas of osteoid, which suggests a chronic as well as an acute process (fig 4). There is a mild inflammatory process in the cells of the mastoid and petrous on the right. Here, too, there may have been a chronic osteitis. It is significant that grossly this lesion was not apparent. After all, the surgeon sees the lesion grossly and in

Fig 1 (case 1)—Base plate in the mentovertical position. Pneumatization has occurred and cells in the mastoid and petrosa on the left have a more washed out appearance.

this case he would have found no creamy pus and he would have found no necrotic bone. With the hemorrhage always present in mastoid operations, this bone would have looked perfectly normal to him.

The mode of invasion of the meninges in this case is problematic. There is no break in the dura, macroscopically. With the low power of the microscope, however, many small cells are seen to drain into the vessels of the dura. Since this is a common finding in ordinary mastoiditis, one is forced to the theory that the virulence of the organism in this case was responsible for the infection of the meninges.

CASE 2—A man aged 21 one week before admission came to Vanderbilt Clinic with a history of five or six days of pain in both ears. Myringotomy was done and considerable relief obtained. The next day there was no drainage from the ears and no more pain. Three days later the patient returned to the clinic and reported that he was feeling well. There was at this time also no drainage from the ears. Six days after the myringotomy, he was admitted to the ear service with a history of severe left sided headache and delirium since the night before. A thin purulent material was discharging from the left ear. Examination of the nose, throat, chest and abdomen

was negative. He had a stiff neck, and a positive Babinski and Kernig reflex. Lumbar puncture showed 5,000 cells with 90 per cent polymorphonuclear neutrophils and an encapsulated diplococcus, which on culture proved to be pneumococcus type III. Roentgen examination showed a clouding of the cells in the left mastoid. A simple mastoid operation was done, but the patient's temperature climbed to 106° F and he died the day following admission. Culture from the left mastoid showed pneumococcus type III, as did a blood culture. Autopsy showed a meningitis, most marked at the base, and no involvement of the large venous sinuses. There was no portal of entry apparent in the dura. Microscopically there was an inflammatory lesion in both petrous tips, but much more on the left than on the right. There was also much less inflammation in the cells about the cavity made by the operation than there was in the cells of the tip. About the carotid canal were dehiscences through which an inflammatory process was invading the wall of the carotid artery. Since the vasa vasorum of the artery drain from the subarachnoid space, it is conceivable that the invasion of the meninges in this case was a retrograde affair along these vessels. Similar cases have been described by Freisner and Druss⁶ and others.

CASE 3—This case was similar, but less acute. A man, aged 24 a divinity student, two months before admission had had "grip" and an acute otitis. Three weeks after myringotomy he developed right sided frontal headache, thought to be sinusitis. Thirty-six hours before admission meningeal symptoms developed. Pneumococcus type III was recovered from a simple mastoid operation and he died four days later.

At autopsy he had a diffuse leptomeningitis. The dura over the mastoid was perforated. More medially, in the neighborhood of the gasserian ganglion, and not connected with the perforation the bone under the dura was soft, necrotic, yellowish and crumbly. Microscopically all the intertrabecular spaces of the bone were filled with a purulent exudate so that the labyrinth was practically sequestered. There was a break in the wall of the internal auditory meatus anteriorly, which was probably the route of invasion of the meninges.

CASE 4—This case ran a somewhat more chronic course. A man aged 45 had had a right sided otitis media off and on for twenty years. One day there was a cessation of the discharge for three or four hours accompanied by excruciating pain on the right side of the head just lateral to the eye. Although the ear began discharging again pain continued. Three days later he was admitted to the medical wards with symptoms of meningitis. In the spinal fluid were 3,000 cells, 90 per cent polymorphonuclear neutrophils but no organisms. A simple mastoidectomy was done and a cholesteatoma found. The right sided headache disappeared and the temperature went down for five days but then the headache reappeared and the patient died two weeks after admission.

At autopsy an abscess was found in the right temporal lobe and purulent material could be seen draining into the meninges from the cells of the petrous. This case is similar to the first and in all probability the drainage was through venous or lymphatic channels into the dural systems.

CASE 5—A woman aged 54 had had a chronic left sided otitis following scarlet fever at the age of 12. She had diabetes and a chronic process in the head of the right humerus, thought to be a typhoid osteomyelitis. She was admitted twice without any mention of headache or any symptoms referable to the ear except chronic discharge. On her third admission a radical mastoidectomy was done to eradicate the chronic focus of infection. After the operation the discharge continued profusely and a revision of the mastoidectomy was done one month later. The discharge still continued. Five months after the operation she came in with severe headache in the frontal and occipital regions definitely lateralized to the left, with many attacks of vertigo and fainting. She came in with a stiff neck, a positive Babinski reflex and tenderness over the mastoid on the left. The spinal fluid contained 700 cells, 60 per cent polymorphonuclears and a hemolytic streptococcus. A new revision of the mastoid was attempted, but she died a few hours later.

6 Freisner, J. and Druss, J. G. Osteitis of the Petrous Pyramid of the Temporal Bone. *Arch. Otolaryng.* 12: 342 (Sept.) 1930.

Autopsy showed a break in the dura over the petrous tip, which had a greenish tinge and was soft and necrotic. Microscopically all the spaces in the left temporal bone were filled with exudate and granulation tissue. She had a purulent labyrinthitis, as well as mastoiditis and petrositis. There was a small area in the endochondral capsule near the second turn of the cochlea, where there was an osteitis of the wall.

CASE 6—A Grecian woman, aged 35, in whom generalized edema had developed at the age of 10 following scarlet fever, at this time also had her first running ear. The edema reappeared with her third pregnancy and the patient was

Fig. 2 (case 1)—Well pneumatized petrosa. Horizontal section through the superior semicircular canal from normal (right) side.

followed in the hypertension-nephritis clinic for two years with a diagnosis of chronic glomerular nephritis. Two months before admission she had an attack of edema, hematuria and vomiting following a cold. She was admitted with a blood pressure of 178 systolic, 114 diastolic, her physical examination being typical of chronic glomerular nephritis. There is no record of any recent trouble in her ears. However, while she was in the ward pain developed in both ears, especially in the right. Myringotomy was done and a green streptococcus with a few colonies of hemolytic streptococcus was recovered. The spinal fluid showed 152 cells and a positive culture for hemolytic streptococcus after many days of growth. Roentgen examination of the mastoid showed slight clouding on the right. The patient became rapidly worse and finally a right simple mastoidectomy was done. A few days later she lost the slight improvement which directly followed the operation, she became comatose, both eyes deviated externally, reflexes were weak on the left, her neck was stiff, and the patient died in coma two weeks after the operation, with a clinical diagnosis of chronic glomerular nephritis.

At autopsy she showed the typical changes of a chronic intracapillary glomerular nephritis and in addition a subdural abscess beneath the right temporal lobe, whose base lay in the petrous tip (fig. 5). The abscess was ruptured and an acute leptomeningitis was also present. Microscopically there was very little inflammatory disease in the cells about the cavity made by the operation. In the petrous tip no cortex was present superiorly where the abscess had lain, and the marrow below showed a chronic osteomyelitis.

COMMENT

Some of these cases presented well pneumatized tips and some did not. In the classification of Kopetzky and Almour,³ those with pneumatized tips would have been called "petrositis" and those with diploic tips would have been called osteomyelitis. In reality the term "petrositis," which means inflammation of the petrous portion of the temporal bone, should be used as a general diagnosis and should have as subheadings: (1) osteitis of the tip, i. e., inflammation of the bone separating the air cells of a pneumatized tip; (2) osteomyelitis of the tip, i. e., inflammation of the marrow and the bone of the tip; and (3) osteitis or osteomyelitis of the case may be of the perilabyrinthine regions. In pathologic material when a diseased tip is only par-

tially pneumatized there is an osteitis of the cells near the middle ear and then if the process proceeds farther an osteomyelitis of the remainder of the bone, while if the tip is wholly pneumatized there is simple necrosis of the bone and mucoperiosteum of the air cells. Both could be called petrositis and both might end in meningitis and death.

The patients in this report all died with the same primary disease, suppuration of the bone about the labyrinth. Presumably this suppuration was an extension from middle ear disease. Why did they die? In microscopic section they all showed some evidence of chronic otitis. In each case there was some sclerotic bone about the hypertympanic space. Is it not possible that previous inflammation produced bone of the type shown in figure 4 in the cells about the orifice of the eustachian tube and so cut off proper drainage from the tip? There are large enough spaces in this bone for infection to enter, but with swelling of the mucoperiosteum secondary to the inflammation, return drainage would be impossible and the process would seek other outlets for escape. This occurs in the mastoid. It is very common to find great destruction of the air cells in cases presenting highly sclerotic antrums and a history of past healed otitis media. This sclerosis of the antral cells has been claimed to be due to faulty development.⁵ In some cases it probably is, but most otologists will agree that often it is obviously the result of inflammatory disease. Sections of these cases show growing bone about the middle ear and good pneumatization elsewhere. This would indicate that the original pneumatization was normal but that bone grew in and blocked off certain pneumatized areas. The anatomic arrangement of this sclerotic bone probably determines the route of invasion of subsequent infections. This is an argument against too conservative treatment of chronic middle ear disease, for certain virulent organisms such as pneumococcus type III and the hemolytic streptococcus pass through or around the sclerotic bone with greater ease and then, as suggested before, drainage is shut off by swelling mucoperiosteum, and a serious condition is produced in distant portions of the bone.

Fig. 3 (case 1)—Well pneumatized petrosa and mastoid filled with exudate. The diseased side. Compare with figures 1 and 2.

There is considerable controversy as to the incidence of petrositis. It is rightly stated that no one symptom or group of symptoms is always pathognomonic of the disease. Pathologic sections from routine autopsies undoubtedly show a higher incidence of exudate in the petrosa than can be apparent clinically. It would seem that a purulent discharge from the middle ear, especially the anterior part of the middle ear, after a satisfactory simple or radical mastoidectomy, is perhaps the most reliable sign of disease in the petrosa. If the

zygoma, mastoid and middle ear have been well cleaned out where else can the discharge come from? If in addition there is trigeminal pain or internal strabismus, or roentgen evidence of destruction in the tip, further surgical intervention is to be considered. After all, entirely too many of these patients die. Out of ninety-five cases of abducens paralysis, in most of which recovery occurred, there were thirteen cases reported by Perkins⁶ as definite petrositis, of these patients, only one lived. The others died of meningitis or complications due to the suppuration in the tip breaking into the posterior pharynx. On the other hand, the forty-two patients with trigeminal pain presumably from other causes recovered.

To illustrate that something conservative can be done even when there is suppuration in the petrous tip, the following case is reported from the service of Prof. Cornelius G. Coakley, through the courtesy of Dr. John Kernan.

G. S., a white boy, aged 7 years, admitted in December 1930, had a typical left otitis and mastoiditis. A simple mastoidectomy revealed a highly pneumatic mastoid and zygoma and many scattered cells filled with yellow pus. The upper part of the posterior wall was broken down as well as the mastoid tip and the sigmoidal angle. After operation the patient had a high temperature for a few days and continued to discharge a serous exudate from the external canal for many months. One year later (Dec. 11, 1931) he was admitted for a modified left radical mastoidectomy. The canal was found to be markedly narrowed by proliferation of bone along the posterior wall. The middle ear and antrum were filled with granulation tissue but the remaining cells of the mastoid were surprisingly healthy. December 27 there was a rise in temperature associated with swelling behind the ear. Reopening the wound under gas and oxygen revealed very little pus in the mastoid cavity but considerable creamy pus in the middle ear. This continued to discharge and produced a large amount of granulation tissue which kept blocking the external canal in spite of frequent curetting and application of silver nitrate. By Feb. 25, 1932, he had begun to complain of pain in the left eye and a

Fig. 4 (case 1)—Osteoid tissue and new bone from the region of the eustachian tube. (Leitz 3 objective.)

low grade fever had developed. He was seen by Dr. Kernan who advised a roentgen examination of the petrous tips.

Dr. Ross Golden reported that films of the skull in the mentovertical position and stereoroentgenograms in the Caldwell position showed the right petrous pyramid to be pneumatized at its tip. A little farther out its shadow was markedly increased in density. The stereoroentgenograms showed an apparent destruction of the upper margin of the left petrous bone beginning at its tip and extending laterally to 2.5 cm. It looked as though this destroyed area began only about 1 cm

inward from the point where the mastoid operation left off. The picture was quite characteristic of petrositis, as described by Taylor.⁷

Dr. Kernan operated, March 9, and reported that the cavity of the previous operation which embraced the mastoid and the middle ear, was found to be full of soft granulations and pus. There was an area of necrosis with a fistula in the roof of the eustachian tube. The fistula led to an abscess supposed to be about the tip of the petrous portion of the temporal bone. The bone underlying the granulation tissue had a soft wormy appearance.

Fig. 5—Base of temporal lobe abscess in petrosal tip. Note absence of cortex and chronic osteomyelitis. Slightly reduced from a photomicrograph with a magnification of 10 diameters.

An incision was made along the line of the previous scar. The ear was turned forward. All the granulation tissues were scraped out of the mastoid cavity and middle ear, and the bony wall was exposed. The facial canal promontory, oval window, carotid canal and eustachian tube were all identified. When the probe was being passed into the eustachian canal a fistula was found leading upward and inward, which exuded about 1 drachm (4 cc.) of thick pus. The tegmen tympani was then taken away and all bone in the region of the eustachian tube exposing the area of the fistula. The cavity was packed with iodoform gauze and the wound was left wide open.

After the operation the pain in the eye disappeared and the aural discharge slowly decreased in amount. In three months the canal was dry, but a small sinus developed which drained serous fluid for still another three months. Now one year after the last operation he is perfectly well and there is no discharge from the ear.

CONCLUSION AND SUMMARY

1. Petrositis is much more common than is generally supposed.

2. Meningitis often brings patients with petrositis to the general medical man or neurologist. The eye symptoms occasionally bring him to the ophthalmologist.

3. Petrositis should be considered in the presence of trigeminal pain, abducens paralysis or an aural discharge after a well executed mastoidectomy.

4. Petrositis should be watched for on the affected side if the mastoid and zygoma on either side is highly pneumatized. The two sides usually pneumatize in the same fashion. If one side becomes sclerotic, especially about the antrum or hypertympanic region, this sclerotic bone may cut off drainage from the deeper and more pneumatized portions of the bone and so lead to pockets in the mastoid or petrosa.

5. Partial pneumatization may lead exudate into the tip where it may pocket or extend into the marrow spaces to produce an osteomyelitis.

6 Petrositis usually subsides spontaneously with adequate drainage from the middle ear. If this is not facilitated by the ordinary mastoid operations, further curetting, especially in the peritubal and perilyabyrinthine regions, will often uncover a pocket of pus.

7 Inadequate drainage of the petrosa may result in a chronically discharging ear or meningitis and death.

8 The method of invasion of the meninges may be manifold, either directly through a subdural abscess or through the veins draining the area, through the labyrinth through the carotid sheath or through the blood stream.

630 West One Hundred and Sixty-Eighth Street

A BETTER METHOD OF TREATING FRACTURES OF THE JAWS

FREDERICK B. MOOREHEAD, M.D.
CHICAGO

The management of regional fractures has engaged the attention of the general surgeon and the specialist throughout the history of surgery. The only answer to any medical discussion is the patient himself. Whatever method contributes most to the well being of the sick or disabled is the method of choice. The principles and methods of modern orthodontia supply the

Fig 1—Common type of jaw fracture

means of managing fractures of the jaws, regardless of the type or extent of injury. The more difficult the case, the more convincing and satisfactory the method becomes. In fractures of other bones, immediate reduction and immobilization are required. In fractures of the jaws with displacement, immediate complete reduction is rarely possible. Here one must be content with gradual reduction. Overriding fractures of the femur present the sort of problem seen in the majority of all jaw fractures. Even the beginning of treatment may be delayed for days or weeks because of complications such as associated fractures of the skull, concussion, serious general injury and infection, and still a good result may be obtained. The orthodontist has given a very important principle in the movement of the roots of teeth in the jaw. He has shown that mechanical irritation, brought about by pressure in regulating teeth, stimulates the activity of the osteoclasts on one side of the root and osteoblasts on the other. This principle is very important in the management of old fractures. Moreover, speaking parenthetically, elastic traction is most useful in the management of large defects in the skin from burns, wounds and the like. Elastic traction used over a sufficient period will make possible immediate removal and closure of a large defect which ordinarily would call for skin grafting, pedicle or tube flap and similar procedures.

The majority of and by far the most frequent complicated fractures of the jaw occur in the mandible. From the cuspid to and including the angle, the greatest number are seen. Fractures of the ramus and condyle are less frequent. Fractures between the cuspids

Fig 2—Reproduction of a fracture recently under management. A, the wire is fashioned to fit the arch and also to extend forward from the cuspid teeth. B, showing the application of the rubber bands. The four teeth in the fractured segment were driven backward and upward.

are usually associated with fractures in the bicuspid and molar region and at the angle. Fractures involving the ramus or condyle usually require no treatment. Displacement is rare. When the patient is informed that his jaw is fractured in these localities, he will exercise sufficient care to insure a good result without immobilization.

Fig 3—A, exact reproduction of appliance used on a fracture seven weeks old before any treatment was undertaken. There was no bony union. B, regulation Angle ribbon arch. C, plaster model made from impressions taken on completion of the case.

The most frequent fracture of the upper jaw is associated with the incisors and cuspids. Direct violence will produce a fracture of the alveolar process with the teeth loosened, broken or knocked out. The

jaw bone proper is not involved. The alveolar process is easily molded back to normal alignment and the teeth are held by a figure of eight silk ligature. When the roots are fractured or the circulation to the pulp is destroyed, the problem is one for the dentist to manage. Unilateral or total fractures of the upper jaw are next in frequency and require very specific management.

My purpose in this brief thesis will be served best by illustrating in detail these various types of fractures

Fig 4—Direction of traction in relation to the line of fracture

and their treatment. I employ elastic traction in practically all cases in which reduction is required. The mechanism employed in reduction frequently serves equally well for satisfactory immobilization. Under traction the parts are brought into proper relation and held with slight movement, which materially aids in repair. Any fracture held in anatomic alignment and held with slight movement will repair more rapidly than one completely immobilized. This factor, when combined with ease, simplicity and accuracy, proves the value of the method.

Figure 1 illustrates a common type of jaw fracture. This figure may represent as well a fracture at any point from the cuspid to the third molar. The short

Fig 5—Skull cap and chin support made with starch bandage hooks and rubber bands adjusted as indicated

fragment is pulled up by the masseter internal pterygoid and temporal muscles while the long fragment is pulled down by the mylohyoid, digastric geniohyoid and external pterygoid. Reduction is easily brought about by a simple appliance. A flat or round wire is

molded with a pair of pliers to fit the arch and is fastened to the neck of the teeth with wire or silk ligatures. Orthodontia rubber bands are attached to the wire on each jaw with silk ligatures. As soon as full occlusion is reached the pull automatically ceases, and the appliance then acts to hold the bones in proper line, and the patient may keep the appliance therefore until union has taken place. After two or three weeks the rubber bands may be removed to see whether occlusion is retained, without help, and if so the appliance may be discarded and a retaining appliance, shown in figure 3 B, may be used if necessary.

Figure 2 illustrates the reproduction of a fracture recently under management. The wire is fashioned to fit the arch and also to extend forward from the cuspid teeth to provide ample space for the application of rubber bands. The four teeth in the fractured segment were driven backward and upward. Reduction, therefore, called for forward and downward traction. This type of appliance may be used in other similar fractures.

Figure 3 A is an exact reproduction of a fracture seven weeks old before any treatment was undertaken. There was no bony union. The marked overriding complicated both reduction and immobilization. This appliance was made by Dr. B. O. Sippy, orthodontist. The rubber bands are attached to the wire extending well outside the teeth on the left. The elasticity of the rubber bands and the spring in the wire furnished double traction. In two days the reduction was complete. This appliance was kept in place a month, when an immobilizing appliance, figure 3 B, was used. This is the regulation Angle ribbon arch. This retaining appliance may be used for lower jaw fractures and is very useful for working people. Full use of the jaw is permitted in eating soft food and talking. Figure 3 C is a plaster model made from impressions taken on completion of the case. This case illustrates one of the most difficult jaw fractures, managed easily and with perfect result by traction.

Figure 4 illustrates the direction of traction in relation to the line of fracture. The roentgenogram will show the line of fracture, and traction should be applied directly in this line.

Total fractures of the upper jaw with downward and backward, downward and forward, or downward and lateral displacement are reduced best by the appliance shown in figure 5. A skull cap and chin support are made with starch bandage, hooks and rubber bands

Fig 6—A lateral displacement, B forward displacement, C backward displacement. In forward and backward displacements traction is always made on both sides. When the displacement is lateral the correction can usually be made by traction on one side. If not an extra rigid wire should be used to include all teeth in each arch. With all teeth in both arches solidly fixed adequate traction may be made from one side. The appliance inside the mouth is used conjointly with the head and chin caps.

adjusted as indicated. In a few days the upper jaw will be pushed up to a normal position. Forward, backward or lateral displacement is usually corrected as the jaw is pushed up. If, however, these displacements are not corrected, additional correction may be used, as illustrated in figure 6.

The head appliance is used with equal success in edentulous jaws. The patient's artificial dentures are placed in the mouth and traction is applied. If the dentures have been broken, they can usually be repaired by the dentist.

The greatest difficulty arises in edentulous jaws when the artificial dentures have been lost or so badly broken that they cannot be repaired. The dentist then can build a vulcanite splint, which may be used instead of the artificial dentures. It is rarely necessary to wire the fragments by an open operation. The partially edentulous mouth will have to be dealt with according to varied conditions.

Unilateral fractures of the upper jaw, with downward displacement, are managed as shown in figure 7. The appliance is placed on the opposite side from the fracture. Traction on the sound side will push the fractured jaw upward until full occlusion is reached.

A simple method of holding lateral stumps of the lower jaw, following resection of the anterior portion, is shown in figure 8. This may also be used to hold one half of the lower jaw following resection of the opposite half. The rubber bands hold the jaw in occlusion with the upper jaw without fixing it. This simple appliance holds the stump or stumps in line during the process of healing and simplifies the introduction of a bone graft later.

A problem of paramount importance is infection. Most jaw fractures are compound, and a majority of these are infected to a lesser or greater degree, in some cases leading to abscess formation and even to necrosis. Vigorous means should be employed as soon as the patient is seen to prevent or control infection. The mouth should be cleansed, first by removing gross deposits of tartar from the teeth, followed by the use of hydrogen dioxide, 25 per cent, and iodosaline. For

Fig 7—Unilateral fractures of the upper jaw with downward displacement

practical purposes iodosaline may be prepared by using one-half teaspoonful of salt to an ordinary glassful of hot water. To this is added from 30 to 40 drops of tincture of iodine. The hydrogen dioxide is used first and then the iodosaline. The mouth should be vigorously rinsed with these solutions every two or three hours. A stronger solution of tincture of iodine should be employed to irrigate the wound or wounds in the soft tissues leading to the point of fracture. For this

a water syringe with a fine metal point is used. The Berlin syringe, made by the S S White Dental Manufacturing Company is ideal. Too much emphasis cannot be laid on scrupulous hygiene of the mouth during the period of treatment.

Another item that needs special attention is the amount of traction to be applied. Until one has had some experience, one will invariably apply too much force. It is far better to apply too little than too much.

Fig 8—Simple method of holding lateral stumps of the lower jaw following resection of the anterior portion

One should start with a moderate amount of traction and watch the case for twenty-four or forty-eight hours. If sufficient progress is not being made, one or two additional bands should be added on each side. Again judgment will have to be exercised, for in one case reduction should be complete in a day or two while in another case one may reasonably figure on a week or more. It follows, naturally, that if too much traction is applied to the slow case, harm is apt to follow. In all cases the teeth must always be fastened *en bloc*. A rubber band must not be attached to an individual tooth, the rubber bands are always attached to the wire, which in turn is attached to all the teeth in the field. The pull, therefore, is equally distributed and will never result in a tender or loose tooth.

The illustrations are intended to emphasize the principle and method of treating fractures of the jaw. The details of making and adjusting the simple appliances are naturally related to the individual case. Talking and taking soft and liquid foods are not interfered with in the use of elastic bands. The mouth may be kept clean and the patient quite comfortable throughout the period of management.

30 North Michigan Avenue

Studies That Widen the Sympathies—Professional work of any sort tends to narrow the mind, to limit the point of view and to put a hall-mark on a man of a most unmistakable kind. On the one hand are the intense, ardent natures absorbed in their studies and quickly losing interest in everything but their profession, while other faculties and interests "rust" unused. On the other hand are the bovine brethren, who think of nothing but the treadmill and the corn. From very different causes, the one from concentration, the other from apathy, both are apt to neglect those outside studies that widen the sympathies and help a man to get the best there is out of life. Like art, medicine is an exacting mistress, and in the pursuit of one of the scientific branches sometimes, too, in practice, not a portion of a man's spirit may be left free for other distractions but this does not often happen. On account of the intimate personal nature of this work the medical man, perhaps more than any other man, needs that higher education of which Plato speaks, "that education in virtue from youth upwards, which enables a man eagerly to pursue the ideal perfection." It is not for all nor can all attain to it, but there is comfort and help in the pursuit even though the end is never reached.—Sir William Osler. *The Master-Word in Medicine*, Address delivered at Toronto, 1903.

PAINFUL HEELS AMONG CHILDREN
(APOPHYSITIS)

HENRY W MEYERDING, MD

AND

WALTER G STUCK, MD

Fellow in Orthopedic Surgery the Mayo Foundation
ROCHESTER, MINN

Since the discovery of roentgen rays less than forty years ago, the study of the pathologic physiology of bone has been markedly facilitated and, as was to be expected, a number of hitherto unknown pathologic conditions of bone have been revealed. Beginning with Osgood's report in 1903, an important group of syndromes, accompanied by certain definite symptoms and by similar epiphyseal changes observed roentgenographically, have been described and elevated to the dignity of specific diseases. Among these diseases are avulsion of the tibial tubercle (Osgood, 1903, Schlatter, 1908), tarsal scaphoiditis (Kohler, 1908), osteochondritis deformans of the hip (Legg, 1910, Perthes, 1910), infraction of metatarsal heads (Freiburg 1914), kyphosis dorsalis juvenilis (Buchmann, 1925) and traumatic malacia of the carpal semilunar bone (Kienbock, 1910). Furthermore, it has gradually become apparent that there are marked similarities in the general pattern of these diseases, for they all seem to follow trauma of one kind or another, occur generally in growing children, affect ununited epiphyses, and are very often accompanied by such characteristic roentgenographic evidence of changes in epiphyses as rarefaction, fragmentation and, later, abnormal calcification.

A seemingly uncommon type of this epiphyseal involvement is epiphysitis of the heel, or the so-called calcaneal apophysitis¹ that is evidenced by painful heels and a limp among young, rapidly growing boys.² To date, less than forty cases of this condition have been reported in the literature, although doubtless many other cases have been seen from time to time that have not been reported.³ As we shall mention later only twenty-one such cases have been seen in the Mayo Clinic.

ETIOLOGY

The epiphysis of the heel is a "pressure epiphysis" and is subject to direct trauma. In this respect it is similar to the epiphyses of the femoral head or vertebral bodies. Furthermore, as in the epiphyses of the tibial tubercle or olecranon, the epiphysis of the heel is also a "traction epiphysis" and is subject to strong

lateral pull from the attached muscles.⁴ Consequently, the heel is unique in being subject both to direct and to indirect trauma. Another distinction of the epiphysis of the heel is that it is encased in tendinous tissue and is situated at a point where a strong pull from the muscles is deflected around an angle. In the transformation from amphibian to mammalian posture the ankle joint became dorsiflexed, the achilles tendon was pulled over the tip of the calcaneus, and gradually a sesamoid bone developed at this point of pressure. In addition, man's erect posture led to a lengthening of the body of the calcaneus, posteriorly, to provide more leverage in the power arm, and to the development of a longitudinal arch in the foot.⁵ These changes in turn brought the sesamoid of the achilles tendon (the calcaneal epiphysis) in close relation to the posterior aspect of the heel. Thus the epiphysis of the heel still retains its strong tendinous attachments above and below, the pull of the muscles of the calf is, for the most part, counteracted by the strong plantar ligaments, and epiphyseal separation is unknown in this region.

Fig 1—Calcaneal epiphysitis. Arrow denotes sclerotic epiphysis with transverse fracture lines.

OCCURRENCE

Epiphysitis of the heel occurs most commonly in boys between the ages of 8 and 12, or during the period of their greatest growth. A history of definite injury may or may not be elicited, although, in any case, these youngsters are usually active and vigorous. The condition ordinarily is bilateral. At first, slight pain at the back of the heel is noted, the patient walks with a limp, and soon he finds it uncomfortable to complete the step. There may also be aching pains along the achilles tendon or in the muscles of the calf. Climbing stairs becomes quite painful and, at times, these children may walk on their toes in order to relax the pull of the achilles tendon.

On examination, the heels are found to be tender posteriorly, and there may be some lateral thickening at the insertion of the achilles tendon. There is voluntary limitation of dorsiflexion of the foot, and forced motion aggravates the pain. Often the children are overweight or present other gross evidence of glandular

sturbance and, as Sevei³ pointed out, they are many times found to be wearing either low sandals or no shoes at all

PATHOLOGIC CHANGES

The most convincing diagnostic feature of all, however, is the characteristic roentgenographic change that occurs with these symptoms. In the lateral view of the foot, the epiphysis of the heel is seen to be fluffy, both eaten, somewhat flattened, or partially fragmented, according to the stage of the disease. Furthermore, there is usually considerable irregularity of the adjacent posterior surface of the calcaneum and a pinched-out appearance in this region due to the alteration of areas of rarefaction with areas of increased density. Finally, the epiphyseal line typically appears cloudy and abnormally irregular. These changes, in varying degree, should assure a positive diagnosis.

Of the pathologic changes that take place in this disease, all are dependent directly or indirectly on disturbance in circulation. This may result from undue trauma to the peripheral nerves in the region that tends to alter the local blood supply. Leriche and Policard's hypothesis was that the injury was in the nature of an "axon reflex," trauma to nerves leading to vasodilatation and more or less permanent vascular imbalance, which in turn produced rarefaction of the bone and local tenderness. Afterward, local edema resulted which accumulated the increased calcification, so clearly seen in the roentgenogram⁶ (fig 1). Bentzon investigated the arterial supply of the calcaneus in this condition and concluded, similarly, that there was a "paralytic hyperemia" of the heel following trauma to nerves that led to proliferative phenomena ("pathologic callus formation"). Others believed the disturbed blood supply followed a partial separation of the epiphysis from muscular pull, or from direct injury to the epiphyseal cartilage.⁸ In any event, all symptoms disappear at the time of union of the epiphysis with the calcaneus and the consequent restoration of an adequate blood supply. Since the epiphysis of the heel normally appears late in the tenth year of life and unites with the calcaneus in the seventeenth year, it is apparent that apophysitis can occur only in this brief period of growth.⁹ Scarlini¹⁰ reported the condition in a woman, aged 22, but there are general features of the story that invalidate his diagnosis.

SYMPTOMS AND INCIDENCE

Apophysitis of the heel can be clearly distinguished from any similar syndrome on the basis of (1) the restricted age incidence (from 10 to 17 years), (2) aggravation of symptoms by forced dorsiflexion of the foot, (3) prompt relief of symptoms by elevation of heel of shoe, (4) absence of general disease, (5) sharply localized tenderness over the attachment of the Achilles tendon, and (6) the characteristic roentgenographic appearance. Inflammation of the bursa under the Achilles tendon produces sharply localized tenderness but no roentgenographic changes. Subcutaneous abscessitis over the heel is quite superficial and follows local irritation. Tenosynovitis of the Achilles tendon usually manifests itself by palpable crepitation on

movement. The painful heel of arthritis occurs in later life, is aggravated by focal infection, other joints may be involved, the tenderness is most often at the attachment of the plantar ligaments, and the roentgenograms usually reveal bony spurs at the points of tendinous insertion. Tuberculosis of the os calcis affects the body of the bone, produces more destruction and leads to more generalized tenderness. Osteomyelitis in this region is accompanied by severe generalized symptoms with acute pain and tenderness, and does not produce roentgenographic changes like those of apophysitis (fig 2).

Twenty-one cases of apophysitis of the heel have been seen at the Mayo Clinic. There were two girls and nineteen boys in the series, including one pair of twin boys. The average age of onset of the disease was 10.2 and the ages ranged from 7½ to 17 years. Only two patients gave any history of a previous fall on the heels, although one patient mentioned a sprained ankle received some time before. One patient was born with marked bilateral clubfoot. Four patients stated that they were more comfortable when they walked on

Fig 2—Calcaneal epiphysitis. Arrow denotes area of osteomyelitis of the calcaneus which had been drained surgically.

their toes, fourteen, or two thirds of the group had bilateral involvement of the heels. One patient had had osteomyelitis of the calcaneus following a severe injury, the intensity of the pain varied from a slight ache or painless lump to a severe disabling cramplike pain in the calves of the legs.

TREATMENT

The treatment of this condition is palliative and, fortunately, is extremely simple. As a general measure, any focus of infection should be removed. Local heat and massage to the feet in the interval of acute pain may relieve the pain somewhat. But the most efficacious treatment consists of elevation of the heels to relieve tension on the Achilles tendon. Heel pads in the shoes are also of benefit, and avoidance of any strenuous exertion is indicated until the acute phase of the condition is over. In the more severe or resistant cases it may become necessary to immobilize the foot, in slight plantar flexion, for several weeks with plaster-of-paris casts. Following this, the heels of the shoes must be raised to prevent any recurrence of symptoms. Symptoms subside promptly under such a regimen and, as mentioned before, the condition disappears when the patients reach the age of 17 years, when the epiphyses become completely united.

COMMENT

There is little doubt that the epiphyses of the heels of healthy children are often injured and that roentgenograms would reveal the typical structural changes of this disease. Very mild symptoms, or none at all, normally divert suspicion from the heels, and roentgenograms are not likely to be taken if symptoms are absent. Beigmann¹¹ found, in a large series of cases, that the characteristic roentgenographic changes of apophysitis were often present when symptoms were completely absent. Moreover, in almost 25 per cent of the cases observed at the clinic the patients were sons of physicians who had easy access to roentgenographic services.

A factor that doubtless contributes to the frequency of this disease is the common modern practice of robust boys engaging in vigorous games in heelless athletic shoes. This undue strain on the calcaneal epiphysis during the period of greatest growth of the bones no doubt engenders an appreciable amount of epiphyseal change that is never discovered. Therefore we feel justified in concluding that destructive changes in the epiphyses of the heels are common among young vigorous children and that failure to recognize them depends on absence of symptoms and consequent neglect in obtaining roentgenograms.

CONGENITAL HEART BLOCK

REPORT OF THE THIRD CASE OF COMPLETE HEART
BLOCK STUDIED BY SERIAL SECTIONS
THROUGH THE CONDUCTION
SYSTEM

WALLACE M. YATER, M.D.

WASHINGTON, D. C.

WILLIAM G. LEAMAN, M.D.

PHILADELPHIA

AND

VIRGIL HEATH CORNELL, M.D.

Major M. C. U. S. Army

WASHINGTON, D. C.

It is becoming increasingly apparent that congenital heart block is not so rare as has been thought. As with many other supposedly rare conditions increasing knowledge and more definite criteria of diagnosis have made physicians more alert to its occurrence. The case to be reported is the third case of complete heart block of congenital origin to be studied by serial sections through the conduction system. The two cases previously studied were reported by Yater¹ and by Yater, Lyon and McNabb². The only other case of congenital heart block studied in a similar manner was one of partial (2:1) block reported by Wilson and Grant³.

The criteria which have been adopted for the diagnosis of congenital heart block are that (1) the auriculoventricular dissociation must be proved by graphic methods in a relatively young individual (2) the brady-

cardia must have been noted at a fairly early age and (3) there must not be a history of any infection which might cause heart block after birth, such as rheumatic fever, chorea, diphtheria or congenital syphilis. The occurrence of syncopal attacks at an early age is fairly good evidence of the existence of the heart block prior to the attacks. The presence of signs of congenital

Fig. 1—Complete heart block the auricular rate being 100 the ventricular 50 per minute

heart disease adds weight to the probability of the congenital origin but it must not be forgotten that congenital heart lesions, such as a patent interventricular septum, may be the seat of acquired endomyocarditis. Signs of congenital heart disease are not necessary however, to establish the diagnosis of congenital heart block since in some instances of congenital cardiac defects signs are absent or not distinctive.

Using these criteria one of us¹ in 1929 collected from the literature thirty-one cases of congenital heart block from among many which had been designated by the authors as such. Some of the others may well have been instances of congenital heart block, but the criteria were not all fulfilled. In 1933 Yater, Lyon and McNabb² in a similar review brought the number up to forty-four. A very probable case reported clinically by Mahaim⁴ as observation XXXII in his book was overlooked. The patient was a girl aged 16 years, whose bradycardia had been noted for four years and in whom physical signs suggestive of patent interventricular septum were elicited. The clinical case of Wood and Rogers⁵ was also not included but probably should have been. The physical signs were those of mitral stenosis, and if this condition existed it may have been acquired in intra-uterine life, since it seems doubtful that it could have developed within the first three months of life when it was discovered. Since then, Blackford and McGehee⁶ have reported the clinical case of a boy aged 19 years who was known to have had a slow pulse since birth; the physical signs were those of aortic regurgitation which makes it difficult to decide whether the lesion was developmental or inflammatory. Ellis⁷ mentioned two cases in a clinical study of heart block but did not report them in detail. The present case has previously been reported without complete anatomic study and without any histologic examination⁸.

Theoretically the cause of congenital heart block is some developmental defect of the bundle of His or

prenatal endomyocarditis or syphilis involving the bundle. Thus far, only the first cause has been demonstrated in the six cases in which necropsy was performed.⁶ In two of these cases histologic studies were not made. The accompanying table gives the salient data in these six cases.

In the cases reported only clinically the diagnosis, made either by the original authors or by Yater, Lyon and McNabb from the description, was patent interventricular septum in twenty-six. In six cases clinical evidence of a developmental defect other than the heart block or transient cyanosis was not found. Patent ductus arteriosus, pulmonary stenosis and aortopulmonary communication were diagnosed in some instances.

Salient Data in the Six Cases of Congenital Heart Block Studied at Necropsy

Case	Author	Sex	Age at Death	Grade of A-V Block	Cardiac Malformations	Histologic Studies
1	Wilson and Grant, 1925 ³	♀	14 mos	Partial 2:1	Rudimentary interventricular septum atresia of root of pulmonary artery patent ductus arteriosus	No complete break in bundle, but fibers buried in fibrous tissue of rudimentary septum
2	Perotti 1923 ⁴	♀	3 days	Not determined	Absence of membranous portion of interventricular septum	None
3	Yater, 1930 ¹	♂	2 wks	Complete	Complete transposition except ventricles	A-V node completely separated from bundle of His by central fibrous body
4	Abbott and Moffatt 1931 ⁵	♂	20 yrs	Complete	Displaced left auricles transposition of great arterial trunks double mitral ostium cor bistratum trilocular right conus stenosis pulmonary arteriovenous aneurysm	None
5	Yater Lyon and McNabb 1933 ²	♂	2 mos	Complete	Large defect in upper middle portion of interventricular septum absence of membranous portion of septum	A-V node in upper edge of defect bundle of His in lower edge and completely separated from node
6	Yater Teaman and Cornell 1934 ⁶	♂	18 hrs	Complete	Absence of interauricular septum and membranous septum and minor anomalies	A-V node completely separated from bundle of His by anomalous central fibrous body

Previously reported incompletely by Leaman

The ventricular rate per minute in the series varied from 20 to 90 and was fastest usually in the youngest patients. On the whole it was considerably faster than in most cases of heart block since most of the patients were infants or children. The degree of auriculoventricular dissociation was complete in all but nine cases and in these it was partial in six alternating from complete to incomplete in two and not determined in one. Symptoms of congestive heart failure were rarely observed. Cyanosis was present in twenty cases and to a marked degree in only six. Clubbing of the fingers

was noted in only three cases. Cardiac hypertrophy ranged in degree from none to marked. Death occurred in nine cases and was sudden in most instances. The oldest patient died at the age of 20 years.

REPORT OF CASE

An infant boy, aged 18 hours at the time of death, was the sixth child of a woman, aged 28. The father and mother and the other children were supposedly free of congenital defects. The mother's prenatal period was entirely uneventful, and the delivery was normal. The Wassermann test of the mother's blood was negative. On delivery which occurred at 3 a. m., May 6, 1932, the child cried feebly and became intensely

Fig 3—Block removed from posterior half of heart for serial sectioning from above downward. Horizontal lines with numbers indicate sites of sections shown in figure 4.

cyanotic. The respiration was very shallow and irregular, and the child was admitted to the Hospital of the Woman's Medical College of Pennsylvania three hours later.

On admission the infant was well developed and well nourished and was apparently a full-term baby. No defects were noted. The length of the body was 51 cm. of the upper extremities 19 cm., and of the lower extremities 19.5 cm. The

¹ Yater: Yater Lyon and McNabb. ² Wilson and Grant. ³ Teaman. ⁴ Perotti. ⁵ D. Blocco cardiaco congenito con vizio di conformazione del cuore. Boll. d. Soc. med. chir. di Pavia 3: 1, 1923. ⁶ Abbott and Moffatt reported in Abbott M. E. in Nelson 1000 Leaf Medicine section on Congenital Heart Disease New York Thomas Nelson & Sons 4: 207, 1932.

weight was 8 pounds (3,630 Gm). There was intense cyanosis of the body generally and of the lips, ears and nails especially. Examination of the lungs showed impaired resonance at the left apex posteriorly. The breath sounds were harsh over both lung fields, and there were many crepitant rales throughout. Substernal inspiratory retraction was present. The left border of the heart was 7 cm from the midsternal line in the fourth interspace. The right border was 2.5 cm from the midsternal line in the fourth interspace. The first sound was obscured by a blowing systolic murmur, and the second sound was weak. The murmur was audible over the entire chest, but the center of intensity was in the second interspace at the left of the sternum. The rate of the heart beat was 40 per minute. There were no thrills. The liver and spleen were not palpable, and the rest of the examination was negative.

The child was taken to the heart station of the hospital, where electrocardiograms were made at intervals for the next few hours. All tracings showed complete heart block, with the ventricular rate of 50 and the auricular of 100, and low

NECROPSY

Except for intense cyanosis of the body generally, and of the lips, ears and nails especially, great congestion of the liver and compression of the lungs by the large and dilated heart, there was nothing of interest except the heart.

Macroscopic Appearance of the Heart—The heart measured 8 cm in its transverse diameter and lay in its usual position. The apex was opposite the seventh rib. The heart was cut in the sagittal plane by the pathologist into anterior and posterior halves. It will be described as it appeared after fixation.

Anterior Surface of the Heart About two thirds of the ventricular portion was composed by the right ventricle and one third by the left. The right ventricle was roughly rhomboid in outline, the left ventricle was roughly triangular. The greatest dimension across the ventricles was 5.5 cm, and the distance from the origin of the pulmonary artery to the apex was 3.8 cm. The two ventricles were separated by the anterior descending branch of the left coronary artery. The aorta and the pulmonary artery were in fairly normal relationship, except that the aorta seemed to arise a little more to the right than usual. When both vessels were held open and looked down into, the pulmonary valve was seen to be to the left of the aortic valve. The aorta was large, and the pulmonary artery was about the same size, if not larger. The ductus arteriosus was not seen in the specimen although it appeared that this vessel was cut just at its beginning. The left auricular appendage was long and narrow, crossing the front of the heart beneath the pulmonary artery and extending half way across the right ventricle. It was 3.3 cm across the front of the heart. The right auricular appendage was larger but not nearly as long, lying just to the right of the root of the aorta, between it and the right extremity of the right ventricle.

Posterior Surface of the Heart About the fifth of the posterior ventricular surface was made up of the left ventricle and two fifths the right, both were roughly triangular in outline. A coronary artery passed down between the two, there was a large branch of the artery going across the left ventricle and several small branches going down across the right ventricle. The posterior surface of the combined auricle was roughly quadrilateral, there was only one apparent large opening for the venae cavae. What appeared to be two large openings for pulmonary veins lay to the left, opposite the caval opening. The bifurcation of the trachea was seen on the specimen just above the left auricle.

Internal Appearance of the Posterior Heart (fig 2A) The two ventricles were equal size and were separated by the interventricular septum, which at its middle was 0.5 cm in thickness and between its upper and lower extremities measured 2.4 cm. The membranous portion of the septum was absent. The walls of the

ventricles were thick, and the musculature was greatly trabeculated, the thickness of each ventricle was about 1.1 cm. The cavity of the right ventricle in this half was 1.5 cm in diameter and about 1 cm deep. Most of the cavity of the right ventricle lay in this half of the heart, whereas most of the cavity of the left ventricle lay in the anterior half. There was no interauricular septum except for a muscular spur in the middle of the roof of the common auricle which was triangular on cross section. This spur was somewhat cone shaped, with the apex pointing downward medial to the caval opening. It was probably a rudimentary septum secundum. There was a well formed tricuspid valve with a papillary muscle in the bottom of the right ventricular cavity between the anterior and posterior leaflets. The mitral valve was well formed. The posterior leaflet as well as the posterior portion of the anterior leaflet was attached to a papillary muscle in the upper posterior wall of the ventricle. There was another but smaller papillary muscle lateral to this

voltage (fig 1). At 12 10 p m oxygen was administered, with slight improvement in the cyanosis. The electrocardiogram was not altered. Electrocardiograms were made at intervals of ten minutes while the following experiments were performed. At 12 15 $\frac{1}{1000}$ grain (0.00006 Gm) of atropine sulphate was given hypodermically. The ventricular rate increased to 60 per minute, the auricular rate remained at 100, and the block persisted, the cyanosis was not improved. At 12 30 the injection of atropine was repeated ($\frac{1}{1000}$ grain). Very soon many premature ventricular contractions began to appear, and the child's color improved considerably. The block persisted, however, and after a short time the premature beats ceased, the ventricular rate returning to 50, the auricular rate remaining at 100.

The child was taken back to the ward and kept in an oxygen tent. A roentgenogram of the chest showed the heart shadow to be very large in all diameters. The child died at 8 o'clock on the evening of its birth.

to which the chordae tendineae of the posterior leaflet were also attached. The median leaflet of the tricuspid valve and the posterior leaflet of the mitral valve were attached together to the upper edge of the interventricular septum. About 0.5 cm above the mitral and tricuspid valves, in the posterior wall of the common auricle, were two small openings about 0.5 cm apart, which were the orifices of the right and left coronary veins, there being no coronary sinus. The common opening of the venae cavae was about 0.5 cm above the right auriculoventricular orifice and was about 0.5 cm in diameter. The cavity of the left part of the auricle was apparently smaller than the right. The two openings already described as pulmonary vein openings were in its posterior wall.

Internal Appearance of the Anterior Half (fig 2B) The cavity of the left ventricle was mainly in this half and was about 2.2 cm deep, and about 1 cm in diameter. Like the right ventricle, it was greatly trabeculated. The interventricular septum ascended in this half to fuse with the anterior wall of the left ventricle anterior to the aortic or anterior leaflet of the mitral valve. This leaflet was attached obliquely posterior to the aortic orifice in approximately its normal position. Part of the other leaflet of the mitral valve was attached laterally in its usual location. There was a small anterior papillary muscle just below this point. The right ventricle showed only a small portion of its cavity opposite the upper third of the interventricular septum. The rounded infundibulum was above this, roughly 1 cm in all dimensions, from which the pulmonary artery emerged in its anterior and medial portion. The median cusp of the tricuspid valve and the anterior portion of the lateral leaflet of the valve were attached along the upper edge of the ascending interventricular septum, and there was an anterior papillary muscle with its chordae tendineae passing across above the upper part of the cavity of the right ventricle between the latter and the infundibulum. Thus there were two complete auriculoventricular orifices with practically normal valves except that they were joined together at the upper edge of the interventricular septum. The aortic and pulmonary valves appeared to be entirely normal. The orifices of the coronary arteries were in normal position.

Microscopic Examination of the Heart—A block of tissue was excised from the posterior half of the heart which included the lower middle portion of the posterior part of the auricles, the major portion of the mitral and tricuspid valves, the upper middle portion of the posterior part of the ventricles, and the upper posterior part of the interventricular septum (figs 2 and 3). This block measured approximately 2 by 2 cm on its upper and lateral edges. It should logically contain the major portion of the conduction system. The block was embedded in paraffin, and serial sections of 8 microns in thickness were made horizontally from above down to the number of 1200. Every tenth section was mounted and stained with van Gieson's connective tissue stain. Later, many of the intervening sections between sections 400 and 600 were mounted and stained, since it was in this region that the main portion of the conduction system was found. The auricular musculature was found from above down to about section 440 to be incompletely divided by a vertical rod of fibrous tissue. A short distance below the orifices of the two coronary veins (from about section 330) the musculature on the right side of this fibrous rod seemed to be somewhat differentiated from that on the left and, as subsequent sections demonstrated, was certainly the counterpart of the auriculoventricular node (1, 2 and 3 fig 4). From about section 440 to section 490 this musculature became gradually surrounded by fibrous tissue, apparently the counterpart of the central fibrous body, and finally it disappeared except for a few fibers at the auriculoventricular junction, where there was practically no muscular communication between auricles and ventricles (4 fig 4). Farther down at about section 500 there began to appear a small bundle of differentiated muscle fibers in the right extremity of the central fibrous body (5, fig 4). This gradually grew larger attaining its maximum at about section 535 (6 fig 4, and fig 5). This bundle was cut somewhat obliquely and ran along the upper edge of the defective interventricular septum from behind forward, at first downward and then more or less horizontally. The fibers were definitely muscle fibers but they were stained lighter than the myocardial fibers; the cross striations were less distinct and the nuclei were smaller. This

bundle, definitely the auriculoventricular bundle of His, gave rise to a narrow left branch, which extended along the left surface of the interventricular septum as far forward as the septum existed in the block (7 and 8, fig 4, and fig 6). The endocardium superficial to the branch was thick, and subjacent to the branch was some fibrous connective tissue, so that the branch was well demarcated. A clear-cut right bundle branch could not be found, although there were certain suggestive groups of fibers. This bundle is very difficult to locate in normal hearts of infants. The left branch was easily followed down the left edge of the septum. The fibers assumed the characteristics of Purkinje fibers, and the bundle became broader and went down across the ventricle in one of the trabeculae to the lateral wall, where it spread out into several trabeculae.

Principal Abnormalities—The main defect of the heart was the almost complete absence of the interauricular septum and of the membranous portion of the interventricular septum. The coronary veins emptied separately into the middle of the posterior wall of the common auricle. The venae cavae had a common opening. The mitral and tricuspid valves were completely formed and were attached medially to the upper edge of the interventricular septum. The aorta and the pulmonary artery had approximately normal relationship.

Fig 5—Enlargement of section 536 showing cross section of bundle of His AVB reduced from a photomicrograph with a magnification of 200 diameters.

Microscopically, it was observed by means of serial sections that there was practically complete absence of the conduction bundle between the common auricle and the ventricles. The central fibrous body had almost completely severed the auriculoventricular node from the auriculoventricular bundle. The bundle of His and the left bundle branch were well developed, but a definite right bundle branch could not be found, although there was a suggestion of one.

COMMENT

The heart in this case is an example of a three-chambered heart with one auricle and two ventricles, or trilobular biventriculosum. Other cases of heart block of congenital origin associated with this anomaly have not been reported. The auriculoventricular dissociation was caused by an anatomic separation of the muscular conduction bridge between the auricular and the ventricular portions of the heart. This anatomic separation was of developmental and not of inflammatory origin. In the great majority of cases of defects of all kinds between the two sides of the heart the small specialized muscular bundle between the auricles and the ventricles is preserved, although its course may be somewhat abnormal. The bundle passes downward and forward from the node of Tawara which lies on the right side of the interauricular septum just anterior

to the coronary sinus. Whether the greater part of the auricular septum, the greater part of the ventricular septum or the greater part of both septums are absent, the bundle enters the ventricles uninterruptedly and divides into branches for these chambers. Its location is always along the upper edge of the muscular portion of the interventricular septum, whether this is normal, slightly defective or only rudimentary, as demonstrated by Monckeberg. In a case anatomically similar in most respects to our case (case of Bostroem-Monckeberg) the auriculoventricular bundle was unbroken.

Monckeberg¹⁰ demonstrated a similar preservation of the conduction pathway in the nearest related anomaly, persistent ostium primum, in which there is a large defect in the lower part of the interauricular septum. Morison¹¹ found a rather anomalous course of the conduction system in a heart with the same defect, but apparently conduction was essentially normal. Yater, Barrier and McNabb¹² studied the heart of a woman, aged 59, at the time of death, who had had Adams-Stokes attacks for nearly three years and in whose

the seventh and the tenth week. The bundle is preserved between the posterior endocardial cushion and the posterior portion of the annulus fibrosis. In our case these structures fused, and muscular communication between auricles and ventricles was destroyed in this region and in all other portions of the auriculoventricular junction where normally no communication is preserved.

SUMMARY

Only six cases of congenital heart block including the one here reported have been studied at necropsy. In all six, congenital defects in the septum between the right and left sides of the heart were present. In four of these cases, studies of the conduction system by serial sections were made. One was a case of partial (2:1) heart block.³ The present case is the third case of complete heart block of congenital origin to be studied histologically. The interauricular septum was almost completely lacking, as was also most of the membranous portion of the interventricular septum. There was practically complete separation of the auricles and ventricles by the central fibrous body in the region where the specialized muscle bundle normally bridges the auriculoventricular groove. The bundle of His was well formed but was disconnected from the auriculoventricular node in this region.

Fig. 6—Enlargement of section 586 showing bundle of His, AVB and left bundle branch LBB, reduced from a photomicrograph with a magnification of 200 diameters.

case electrocardiographic records showed progressively increasing degrees of heart block during this time. The heart had a persistent ostium primum but the course of the conduction system was essentially normal. The acquired heart block was due to fibrosis, apparently from strain, of the upper edge of the interventricular septum where the bundle of His was located.

The reason for the almost constant preservation of the muscular connection between the auricles and ventricles probably lies in the fact that the special bundle appears in the fifth week of fetal life,¹³ whereas the membranous separations between the auricles and the ventricles and between the ventricles take form between

THE ARTIFICIAL TRANSMISSION OF MALARIA AMONG INTRAVENOUS DIACETYLMORPHINE ADDICTS

1. PRELIMINARY NOTE ON THE USE OF ATABRINE IN MALARIA

EMANUEL APPELBAUM, MD

Associate Visiting Physician, Bellevue Hospital; Bacteriologist, Research Laboratory, New York City Health Department; Instructor in Medicine, New York University and Bellevue Hospital Medical College

AND

BEN B. GELFAND, MD

House Physician, Bellevue Hospital
NEW YORK

It is astonishing that until recently the relationship of malaria to drug addiction has been either not recognized or not fully appreciated. In 1929, Biggam¹ reported ten cases of malignant malaria associated with the administration of diacetylmorphine (heroin) intravenously. In 1930, Biggam and Arafat² reported on a series of more than 100 cases of artificially induced malaria. All their patients were inhabitants of Cairo, Egypt. To the best of our knowledge, the first contribution on this subject in this country was made by Eaton and Feinberg³ in 1933. These authors reported two cases of malaria in intravenous diacetylmorphine addicts under their observation at the Cook County Hospital, Chicago.

During the past six months thirty-nine addicts admitted to Bellevue Hospital were found to be suffering from malaria. Ten of these patients were observed in the Fourth Medical Division and formed the basis of our study.

REPORT OF CASES

CASE 1—W. W., a man, aged 35, a sailor, admitted to the hospital, Oct. 13, 1933, complained of severe intermittent chills.

From the services of Dr. Harlow Brooks and Dr. Herman O. McEnthal, Fourth Medical Division. Dr. Charles H. Nammack, director.

and fever of four weeks' duration and progressive swelling of the lower extremities for the past two weeks. He had been taking diacetylmorphine intravenously for the past five years and had been in the habit of sharing his hypodermic outfit, known as "the works," with other addicts. He had been residing in New York City for the past year. Five years before, while in Africa, he contracted malaria, for which he was treated and apparently cured. He remained perfectly well until the onset of the present illness.

On physical examination he appeared well nourished. There was moderate edema and pallor of the face. Moist rales were present at the bases of both lungs. The heart was normal. The blood pressure was 124 systolic and 50 diastolic. The liver and spleen were enlarged, and their edges were felt about four fingerbreadths below their respective margins. There was marked edema of the right arm and both legs. Both antecubital fossae and the upper halves of the flexor surfaces of the forearms showed numerous scars of previous puncture marks surrounded by dark greenish pigmentation along the course of the veins. Some of the veins appeared thickened and cordlike. The reflexes were normal. The temperature curve, showing abrupt rises every seventy-two hours, suggested the diagnosis of quartan malaria. This was confirmed by study of the blood smear, which showed the presence of both rings and adult forms of the quartan plasmodium. The urine showed a moderate trace of albumin and a few casts. The red blood count showed 3,200,000 cells with 60 per cent hemoglobin. The white blood count was 7,000, with 74 per cent polymorphonuclears and 24 per cent lymphocytes. The blood chemistry showed a nonprotein nitrogen of 32 mg and a sugar of 84 mg per hundred cubic centimeters.

October 25, following four paroxysms of chills and fever, the patient was put on quinine therapy and made an uneventful recovery.

The relationship of the malaria to the intravenous administration of diacetylmorphine in this case is suggestive but not clear cut. It is impossible to say whether the original attack was transmitted by a mosquito or was artificially induced. It is also hard to decide whether the present illness is a recurrence of the previous attack of malaria or newly acquired in association with the diacetylmorphine habit.

CASE 2—G M., a man, aged 46, admitted to the hospital, Nov. 4, 1933, complained of headache, general malaise, stiffness of the neck, and chills and fever of three weeks' duration. The chills occurred every third day. He had been taking diacetylmorphine intravenously for the past seven years, sharing a hypodermic outfit with other addicts. He had always lived in New York City and had never visited any malarial districts. There was nothing relevant in the past history.

On examination, he appeared cachectic and pale. His neck was stiff and motion was limited in every direction. There were, however, no Brudzinski or Kernig signs. The reflexes were all normal. The heart was normal. The blood pressure was 70 systolic and 40 diastolic. There were diffuse coarse rales throughout the lungs. The spleen was just palpable. Both forearms showed typical puncture marks and scars with pigmentation along the course of the thickened veins. There was moderate edema of both legs. The temperature was 102 F on admission and rose to 105 F within thirty-six hours. The white blood count was 20,000, with 85 per cent polymorphonuclears. The red blood count was 2,230,000, with 65 per cent hemoglobin. The nonprotein nitrogen was 47 mg per hundred cubic centimeters. The spinal fluid was clear and showed no increase in globulin, normal sugar content, and 4 cells. Examination of the urine was entirely negative. The blood smear showed numerous rings and adult forms of the quartan plasmodium. The blood culture was negative.

November 9, he became irrational and delirious. The same day a diffuse purpuric eruption over both legs was observed. Quinine therapy was instituted at this time.

November 11, his general condition was distinctly worse. On examination he was comatose and jaundiced, had generalized spasticity of all the muscles and showed signs of pneumonia in both lungs. Another spinal tap performed yielded a normal fluid. He died, November 13.

In this case, it seems to us, there can be little doubt that the malaria was transmitted accidentally in connection with the intravenous administration of diacetylmorphine. The marked leukocytosis was due either to the severe malarial infection or to the pneumonia. It is somewhat difficult to explain the marked muscular spasticity and neck rigidity, but it is not unlikely that these signs of meningeal irritation were features of a severe toxemia. His jaundice likewise was probably a toxic manifestation.

CASE 3—R C., a man, aged 38, a sailor, was admitted to the hospital, Jan. 1, 1934, in a comatose state. The history obtained after his recovery was as follows:

He was born in Puerto Rico but had never had malaria before and, in fact, had never been sick before. He became a snuffer of diacetylmorphine in September 1933. Early in December he commenced injecting solutions of diacetylmorphine by means of an eye dropper into puncture wounds made with a safety pin. He received his first intravenous injection of diacetylmorphine on December 29. This was administered by another addict employing an eye dropper attached to a needle. December 31, he began to have headache, chills and fever. Jan. 1, 1934, he was admitted to the hospital in a deep stupor.

Physical examination on the day of admission showed the patient to be in deep coma. There was extensive herpes labialis. The heart was normal. The blood pressure was 114

Fig. 1—Estdio autumnal parasites. Ring forms are seen at A, B and C and gametocytes are seen at D.

systolic and 78 diastolic. The lungs were clear. The spleen was enlarged to four fingerbreadths below the left costal border. Both arms and legs showed many puncture marks, and one of these was directly over a vein in the left antecubital fossa. There was slight rigidity of the neck but negative Brudzinski and Kernig signs. All the deep reflexes were exaggerated. The pupils were equal and reacted to light. Examination of the fundi showed moderate hyperemia of the finer vessels of the disks, giving them a marked rosy brilliant color. The larger vessels showed no changes and there were no hemorrhages, exudate or edema. The temperature was 104 F, the pulse 120, and respirations 22.

The white blood count was 32,000 with 73 per cent polymorphonuclears and 23 per cent lymphocytes. Lumbar puncture yielded 20 cc of clear fluid under increased pressure. The spinal fluid on examination showed 252 cells, mostly mononuclears, globulin 2+ albumin 2+ and sugar 3+. Urinalysis showed albumin 2+, an occasional hyaline cast, and red and white blood cells. A study of the blood smear showed an overwhelming number of malarial plasmodia. Most of these were ring forms, but several gametocytes were also found (fig. 1). This was definitely a case of the pernicious form of estivo autumnal malaria.

Shortly after admission 40 grains (2.6 Gm) of quinine sulfate in suspension was administered by stomach tube.

January 2, the patient's condition remained unchanged with persistence of deep stupor and high temperature. On this date 25 grains (1.6 Gm) of quinine dihydrochloride was administered intravenously in divided doses.

January 3, the patient was still in coma with no improvement in the general condition. Ten grains (0.6 Gm) of quinine dihydrochloride was again given intravenously. On the afternoon of the same day when he appeared to be going rapidly downhill, the intravenous administration of atabrine was resorted to. The first dose was 150 mg and was given at 3 p. m. Four hours later he was given 200 mg of the drug. About midnight he was given another dose of 100 mg.

January 4, in the early morning hours the patient began to show definite improvement. His temperature dropped to 100 F, and he had lucid intervals. One hundred milligrams of atabrine was again given intravenously. In the afternoon he was quite clear mentally, and his temperature was 99 F. The use of atabrine by mouth was begun on this date the dose being 1½ grains (0.1 Gm) three times a day, and it was continued for the next five days.

January 5 the patient's general condition was very satisfactory. He was quite clear mentally and his temperature was normal. The spleen was much smaller and softer. A spinal tap yielded 15 cc of clear fluid under normal pressure. On examination this fluid was practically normal. The white blood count was now 8,400 with 65 per cent polymorpho-

Fig. 2—Numerous schizont and malarial ring forms are seen at A, B and C.

nuclei and 31 per cent lymphocytes. The red blood count was 3,800,000 with 70 per cent hemoglobin. No malarial parasites were found in the blood smear. The nonprotein nitrogen was 45. Both the blood and spinal fluid Wassermann tests were negative.

From this time on the patient's condition remained satisfactory. Repeated blood smears failed to show the schizonts, but gametocytes were repeatedly found. In order to eradicate the gametocytes, we proposed to put him on plasmoquine as recommended by many workers,⁴ but January 28 the patient insisted on obtaining his discharge.

This case was cited in detail in order to illustrate some interesting and important points. This was a typical example of cerebral malaria and was by far the most severe and malignant form of the disease which did not end in death. It seems to us that there can be little doubt that in this case the malarial infection was artificially induced, Dec. 29, 1933 by an unclean hypodermic outfit. So far as we know, this is the first record in this country of the intravenous use of atabrine for malaria. It is of course difficult to decide whether the atabrine alone or its use in combination with the quinine was responsible for the recovery.

Certainly there was no improvement in the clinical picture before the atabrine was administered. This drug may, therefore, be regarded at least as a contributory factor toward the recovery of this patient.

CASE 4—J. C., a man, aged 20, admitted to the hospital Jan. 9, 1934, complained of progressive swelling of the face, hands, genitalia and legs of three weeks' duration. He also had marked nocturia. For the past two months the patient had had episodes of chilly sensation followed by fever, occurring every third day. For the past sixteen months he had been taking diacetylmorphine intravenously, often sharing the hypodermic outfit with other addicts.

He was born in Maine but spent his childhood in North Carolina, where, at the age of 8 years, he claimed to have had an attack of malaria. He had lived in New York City for the past three years and had been free from any febrile attack from his childhood to the present illness.

Physical examination showed him to have a pasty appearance, with puffiness of the face and eyelids. He also had marked edema of all the extremities and evidence of ascites. There were the typical puncture marks over the forearms. The heart showed no abnormal signs. The blood pressure was 130 systolic and 78 diastolic. The lungs had moist rales at both bases. The reflexes were normal. The eyegrounds showed no hemorrhages or other abnormal manifestations. The temperature was normal on admission but later presented a typical quartan curve.

The white blood count was 4,800, with 56 per cent polymorphonuclears and 44 per cent lymphocytes. The red blood count was 3,200,000, with 60 per cent hemoglobin. On the blood smear there were numerous adult and ring forms of the malarial parasite. The urine examination on several occasions showed a moderate amount of albumin, a few granular casts and an occasional red and white blood cell but failed to show the presence of doubly refractile lipid bodies. The nonprotein nitrogen was 36, cholesterol 130, sugar 100, uric acid 3.7 and creatinine 1.7 mg per hundred cubic centimeters of blood. The serum albumin was 2.8 and the globulin was 1.9 per cent.

January 14, after the diagnosis of quartan malaria was definitely established, the patient was started on atabrine therapy. He received 1½ grains three times a day for a period of ten days. On the fourth day of treatment he showed marked improvement. His temperature was normal and the edema had practically disappeared. The spleen was now palpable. No malarial parasites were now found. The urine was negative except for an occasional finely granular cast. His condition remained satisfactory and he was discharged, January 26.

It seems to us that the patient's vague history of malaria in childhood is not in any way related to his present illness, as there was an interval of well being of more than twelve years. The relationship of his malaria to the injections of diacetylmorphine is there fore quite probable. In this connection it is of importance to note that a diacetylmorphine addict in another service with whom he shared injections was also suffering from quartan malaria at the same time. This case also illustrates that nephritis is an important complication of malaria. The prompt response of this patient to atabrine was indeed gratifying.

CASE 5—A. C., a man aged 34, admitted to the hospital, Jan. 10, 1934, complained that for the past week he had had attacks of chills and fever, which occurred from one to three times daily. For the past four days he had noticed marked swelling of the face, abdomen and extremities. He also had nocturia.

He had been a drug addict for the past fifteen years and for the past twelve years had been in the habit of taking diacetylmorphine intravenously in the usual manner. Since 1922 he had been a resident of New York City but prior to that time he had traveled in the southern states, where he contracted malaria. When he came to New York he was still suffering from the active phase of the disease and was treated intensively with quinine and apparently was cured within a

⁴ Barber, M. A. and Komp, W. H. W. Ann. Rep. M. Dept. United Fruit Company 16: 54, 1927. Barber, M. A. Komp, W. H. W. and Newman, B. M. Pub. Health Rep. 44: 1409 (June 14), 1929. Macphail, N. P. Ann. Rep. M. Dept. United Fruit Company 18: 13, 1929. Manson-Bahr, Philip. Proc. Roy. Soc. Med. Sect. Trop. Dis. 20: 919 (April) 1927. Lancet 2: 496 (Sept. 8) 1928.

short time. From that time on he had been free from all symptoms and signs referable to malaria up to the present illness, which apparently developed after he shared injections with an addict who at that time had similar symptoms. After the onset of the malarial infection, the patient shared injections with his roommate, who also developed symptoms suggestive of malaria.

On examination, the patient appeared acutely ill, with pronounced swelling of the face, especially about the eyelids. The heart showed no abnormal signs. The blood pressure was 128 systolic and 70 diastolic. There were moist rales at the bases of both lungs. There was marked edema of the torso, scrotum and lower extremities. There was also evidence of ascites. On the forearms there were the typical puncture marks with marked thickening of the veins. He was clear mentally and his reflexes were normal. Ophthalmoscopic examination showed hemorrhages in both fundi. Most of the hemorrhages were flame shaped, while one was oval with a pale center. The temperature on admission was 105 F and dropped to normal the next day. Subsequently the patient had an irregular fever, ranging between 101 and 105 F.

A study of the blood smear showed many plasmodia. Most of these were ring forms, but there were also a few gametocytes. The diagnosis was estivo-autumnal malaria. The urine examination on several occasions showed a heavy trace of albumin, no casts and an occasional white blood cell and no doubly refractile lipoids. The phenolsulphonphthalein excretion was 45 per cent in two hours. The nonprotein nitrogen was 27 and the sugar was 110 mg per hundred cubic centimeters. The serum albumin was 2.4 and the globulin, 2.2 per cent. The white blood count was 3,200 with 71 per cent polymorphonuclears and 29 per cent lymphocytes. The red blood count was 2,850,000, with 55 per cent hemoglobin.

On the fifth day of his stay in the hospital the patient was put on atabrine therapy, receiving $1\frac{1}{2}$ grains three times a day. This was continued for ten days. The patient responded promptly to the treatment and the clinical improvement was rapid. On the fourth day of treatment no plasmodia could be found in the blood smear and examination of the urine was entirely negative. He was discharged from the hospital, January 26, in excellent condition.

In this case the relationship of the malaria to the drug addiction is somewhat uncertain. However the long interval of well being that followed his first attack of malaria and the details of his present illness suggest very strongly that the recent attack of this disease was conveyed by intravenous injections of diacetylmorphine. This case also presents some interesting clinical features. There was very pronounced involvement of the kidneys, as indicated by the albuminuria and marked generalized edema. The eveground changes were unusually interesting. The response to atabrine was quite prompt.

CASE 6—F W, a man aged 26, admitted to the hospital, Jan. 28, 1934, complained of chills and fever for the past three weeks. The chills occurred at irregular intervals. He was born in Florida, where at the age of 15 he had an attack of malaria, which was cured with quinine. He had had asthma for many years. He had been living in New York City for the past three years and for the past two years he had been taking diacetylmorphine intravenously.

On examination, he appeared thin, pale and pasty. Apathy was quite pronounced. There was herpes labialis. There were marked generalized twitchings. The lungs presented the usual signs of chronic bronchitis. The heart presented no abnormal signs. The blood pressure was 76 systolic and 44 diastolic. The spleen was not felt. On his forearms were the typical puncture marks along the course of the veins. There was moderate rigidity of the neck, but there were no Kernig or Brudzinski signs. The knee jerks were active. The fundi showed increased tortuosity of the vessels with moderate congestion of the disk capillaries and a small flame-shaped hemorrhage on the left side. The temperature on admission was 100.5 F but mounted to 106 F the next day. It remained irregularly high, ranging between 102 and 105 F until specific therapy was instituted.

Examination of the urine was entirely negative. The blood chemistry showed a nonprotein nitrogen of 35 and a sugar of 125 mg per hundred cubic centimeters. The white blood count was 6,800, with 78 per cent polymorphonuclears and 22 per cent lymphocytes. The red blood count was 3,600,000, with 60 per cent hemoglobin. The blood smear showed numerous malarial plasmodia, most of which were ring forms and a few crescents. The diagnosis of estivo-autumnal malaria was definitely established. The signs of moderate meningeal irritation and the apathy suggested early or impending cerebral involvement. This impression was confirmed by analysis of the spinal fluid, which showed 25 cells, mononuclears, a slight increase in albumin and globulin, a normal sugar, and a negative Wassermann reaction.

January 31, three days after admission the patient was started on atabrine receiving $4\frac{1}{2}$ grains (0.3 Gm.) three times a day. February 1 there was decided improvement. The temperature was normal and the apathy was much less pronounced. On this day he received 3 grains (0.2 Gm.) of atabrine three times. A yellowish tinge of the sclerae and of the skin was noted the same day. This was regarded as an atabrine manifestation. From this time on the clinical improvement was progressive. The temperature remained normal and he was quite clear mentally. The yellowish discoloration of the skin, however, persisted for several days. The atabrine was continued in doses of $1\frac{1}{2}$ grains three times a day until February 6.

February 7 the temperature suddenly rose to 104 F. Examination on this day showed early signs of pneumonia. The blood smear was negative for malarial plasmodia. Within a few days there were frank signs of consolidation of the left lower lobe associated with marked toxemia. A typing of the sputum showed pneumococcus type 30. The blood culture was negative. The blood count was 5,300, with 88 per cent polymorphonuclears and 12 per cent lymphocytes. He died, February 12.

In view of the fact that this patient had been entirely well for eleven years following his previous attack of malaria it is fair to assume, it seems to us, that his recent attack of this disease was conveyed by a contaminated hypodermic outfit. There was definite evidence in this case of early cerebral involvement. The prompt response to atabrine was indeed striking, as evidenced by the sudden drop in temperature and the marked improvement in the mental picture. The other interesting features in this case were the ocular changes and the development of pneumonia. The pulmonary complication was undoubtedly the cause of death.

CASE 7—J D, a man aged 35, was admitted to the hospital Feb. 9, 1934, in a state of deep coma. The history was obtained from his brother who stated that the patient had collapsed suddenly shortly before admission. He was known to have been an intravenous drug addict for a number of years. He had always lived in New York City and had never had malaria before.

Physical examination showed the patient to be in deep coma. The temperature was 105 F. The heart was somewhat enlarged to the left and the sounds were of poor muscular quality. The veins of the neck were dilated. The blood pressure was 138 systolic and 74 diastolic. The lungs were clear. The spleen could not be felt. On the thighs were shallow scars of old puncture marks. In the antecubital fossae overlying the veins were many puncture marks, surrounded by bluish brown pigmentation. There was slight rigidity of the neck. There was moderate spasticity of the extremities and hyperreflexia. The examination of the fundi revealed marked engorgement of the fine vessels of the disks, giving them a brilliant red appearance. The disk edges were somewhat indistinct. There were no hemorrhages or edema. The larger retinal vessels appeared normal.

The urine showed a heavy trace of albumin, many hyaline and granular casts, and a few white and red blood cells. The white blood count was 16,000 with 74 per cent polymorphonuclears and 26 per cent lymphocytes. The red blood count was 4,800,000 with 70 per cent hemoglobin. The blood smear showed numerous malarial ring forms (fig. 2) and a few gametocytes. The blood culture was negative. The spinal

fluid came out under increased pressure, was clear, contained 50 cells, and showed a 2+ albumin and globulin, and a normal sugar.

The diagnosis of estivo-autumnal malaria, cerebral form, was definitely established. The patient was promptly put on atabrine therapy, the first dose being 200 mg intravenously. The same dose was repeated three hours later. Four hours after admission, signs of pulmonary edema and marked circulatory collapse developed. The pulse was very rapid and thready. The blood pressure dropped to 80 systolic and 60 diastolic. The skin was cold and clammy. Active stimulation was resorted to, but the patient died several hours later.

There can be little doubt that in this case the malarial infection was transmitted by means of a contaminated hypodermic outfit. The most striking clinical feature in this case was the severe cerebral involvement. The eyeground changes were quite characteristic. There was also evidence of renal involvement. Death was obviously due to complete circulatory collapse.

CASE 8—II M, a man aged 22, was admitted to the hospital Feb 9, 1934, in a stuporous state. A complete history could not be obtained. He was known to have been an intravenous drug addict for the past seven years. The present illness began two days before with marked drowsiness which progressed rapidly to complete stupor.

On examination, the patient was in a state of coma. The respirations were shallow but the lungs were clear. Except for a short systolic murmur at the apex the heart was normal. The blood pressure was 130 systolic and 80 diastolic. The spleen was palpable. There were numerous hypodermic puncture marks along the course of the veins of both forearms. All the reflexes were exaggerated. There was a positive bilateral Babinski and Oppenheim reflex. The fundi showed marked engorgement of the small vessels of the disks giving them a brilliant red appearance. The disk edges were indistinct. There was no edema or changes in the larger retinal vessels. There were a few scattered flame-shaped hemorrhages in the left eye. The temperature was 102 on admission and within twelve hours mounted to 108.6 F. There was a proportionate rise in pulse from 90 to 160. The respirations were 36.

The urine showed a slight trace of albumin and bile. The white blood count was 10,500 with 68 per cent polymorphonuclears, 26 per cent lymphocytes and 6 per cent transitionals. The red blood count was 2,800,000, with 70 per cent hemoglobin. The nonprotein nitrogen was 40 mg per hundred cubic centimeters of blood. The spinal fluid was clear, contained 15 cells and had a 2+ albumin and globulin and a normal sugar. The blood culture was negative. A study of the blood smear showed a small number of malarial parasites, ring forms and gametocytes.

As this was obviously a case of the cerebral form of estivo-autumnal malaria, the patient was immediately given 200 mg of atabrine intravenously. During the following twenty-four hours, he received 700 mg of the drug intravenously in divided doses. The patient however failed to respond to the intensive therapy. His condition became rapidly worse. He had several convulsive seizures with projectile vomiting, and a marked hyperpyrexia developed. He died approximately twenty-four hours after admission.

In this case the malaria was very likely related to the intravenous drug addiction. Of course this relationship could not be established with absolute certainty because of the inadequate history. This case was very interesting from a number of angles. It was the first instance of cerebral malaria in which convulsions and hyperpyrexia were outstanding symptoms. It is also to be noted that, in spite of severe clinical manifestations, very few parasites were found in the peripheral blood. Finally, the eyegrounds presented typical changes.

We had two other intravenous diacetylmorphine addicts who were admitted to the hospital in a state of deep coma and died shortly after admission. The diag-

nosis of malaria in these cases was not made clinically but was established at necropsy.

COMMENT

The artificial transmission of malaria is now a recognized fact. Many persons have been inoculated with the disease for therapeutic purposes, especially in the treatment of dementia paralytica. Wenyon⁵ and Netter⁶ report instances of malaria transmitted by nonsterile injection of arsphenamine. Accidental transmission of the disease in blood transfusions has been noted by Korabelnikoff⁷ and Decourt⁸. According to Bass,⁹ malaria results almost every time when injected intravenously, less frequently when it is injected intramuscularly or subcutaneously. It is not surprising, therefore, to find this infection disseminated among intravenous drug addicts who share injections by means of a nonsterile hypodermic outfit.

In our series, there can be little doubt that malaria was artificially induced in cases 2, 3 and 7. In case 4, the relationship between the malaria and the injections of diacetylmorphine is very probable. In cases 1, 5 and 6, the relationship between the drug addiction and the present attack of malaria is somewhat less certain. Of course, no definite conclusions can be drawn in cases 8, 9 and 10, because of the inadequate histories.

There is therefore sufficient evidence to show that a number of intravenous diacetylmorphine addicts have accidentally acquired malaria while sharing injections with other addicts who were afflicted with this disease. Furthermore, the number of such cases is apparently on the increase. In this connection, one must also bear in mind the fact that anopheles mosquitoes are known to breed even in the northern section of the United States. The possible dissemination of malaria in the northern parts of the country must therefore be seriously considered. This extraordinary manner of malarial transmission may thus assume importance as a public health problem.

In this connection, it may be of interest to describe briefly the method of group injection practiced by the drug addicts. The drug used is exclusively diacetylmorphine and is invariably administered intravenously. The addicts usually congregate in groups. The drug is put into a tablespoon and tap water is added. The contents are then brought to a boiling point by using a candle or match flame. A small piece of cotton is put into the tablespoon and the solution is drawn up through the cotton into a large medicine dropper. Strips of paper are wrapped around the tip of the dropper in order to fit the needle. After a tourniquet is applied to the arm, the needle is inserted into one of the antecubital veins. When they observe the flow of blood into the eye dropper, the tourniquet is released and the solution is injected into the vein. The hypodermic outfit is never sterilized and is passed around from one addict to another.

From a clinical point of view these cases were extremely interesting. The severity of the malarial infection in most of the patients was rather striking. In only one instance was the disease comparatively mild. The mortality was unusually high, six of the ten patients having died.

As to the causative plasmodium, three of the cases were of the quartan variety, while the remaining seven were estivo-autumnal in type.

The cases with cerebral manifestations were by far the most serious ones. The term "cerebral malaria" was applied to this group. Six of our cases were of this type. They were all caused by the estivo-autumnal parasite. All but one of our patients with cerebral malaria were in a comatose state on admission. The exception was a patient who showed marked apathy but who was not in a stupor. Five of the six patients died. However, one of the deaths was due to pneumonia and not to the moderate degree of cerebral involvement, which was apparently controlled with antimalarial therapy. This was confirmed at necropsy. The seriousness of the cerebral form of malaria is therefore quite apparent.

The occurrence of nephritis as a complication of malaria is a matter of common observation. Indeed, there have been many contributions on the subject. Particularly noteworthy are the recent reports by Giglioli,¹⁰ Lorando¹¹ and Goldie.¹² According to Goldie, nephritis in malaria may be either hydremic in type, with edema as the dominant clinical feature or azotemic, with nitrogen retention as the cardinal symptom. He believes that renal complications occur most frequently in the quartan form. Malarial nephritis, of course, is not to be confused with the albuminuria often observed during the febrile attacks of the disease.

In our series there was definite clinical evidence of nephritis in cases 1, 4, 5 and 7. These patients showed in the urine moderate or marked amounts of albumin, casts and red and white blood cells. In cases 1, 4 and 5 there was also marked edema. None of these patients had azotemia or hypertension. Two of the patients had estivo-autumnal and two had quartan malaria. Under treatment the symptoms of nephritis were promptly relieved in cases 1, 4 and 5. Many observers have commented on this remarkable response of the renal symptoms to the antimalarial therapy.

In the modern literature on malaria there are very scant references to the eyeground changes. The older writers, however, especially those of the German and French schools, investigated the subject very thoroughly. Raynaud¹³ in 1892, in an excellent monograph on the ocular disturbances in malaria described the fundus changes in great detail. He emphasized that the most common pathologic finding is hyperemia of the disks and that this change is in most instances responsible for the transitory amblyopia. The hyperemia of the finer vessels gives the disks a rosy brilliant appearance. This remarkable finding was observed in cases 3, 6, 7 and 8 of our series. In the last two of these cases there was also a blurring of the edges of the disks. It may be of interest to note that Peunoff¹⁴ in 1879 was probably the first to describe accurately the disk changes in malaria.

Another remarkable change is the presence of retinal hemorrhages which occur most often in the course of the larger vessels, although they may occupy the disk. Gueneau de Mussy¹⁵ in 1872 was the first to describe

these hemorrhages in malaria patients. Poncet¹⁶ made a thorough study of the subject in 1878 and reported the presence of these hemorrhages in 10 per cent of his cases. There was also an excellent contribution on these fundus changes by Sulzer¹⁷ in 1890. More recently, this subject was discussed by Collins and Mayon,¹⁸ who mentioned two types of retinal hemorrhage—small peripheral and large central ones. The latter these authors assert, are due to blockage of the retinal vessels by the parasites.

We observed retinal hemorrhages in three of our patients (5, 6 and 8). Most of the hemorrhages were rather small and flame shaped. In one instance there was a large oval hemorrhage with a pale center.

It should be noted that none of the patients showed marked papilledema or the presence of exudate. Engorgement and increased tortuosity of the larger retinal vessels were observed in only one instance.

It may be of interest to discuss briefly the blood counts in our series. As will be noted in the accompanying table a moderate degree of anemia was almost a constant feature. On the other hand, the classic leukopenia was rather the exception than the rule, being present in only two instances. A marked leukocytosis was noted in two cases. One was a patient with cerebral malaria who recovered, and the other was a patient who had a pneumonic process.

Blood Counts

Case	Red Blood Cells	Hemoglobin per Cent	White Blood Cells	Polymorpho-nuclears	Lympho-cytes
1	3,200,000	60	7,000	74	24
2	2,230,000	65	20,000	85	15
3	3,800,000	70	32,000	73	23
4	3,200,000	60	4,800	56	44
5	2,550,000	55	3,200	71	29
6	3,600,000	60	6,500	78	22
7	4,500,000	70	16,000	74	26
8	2,500,000	70	10,500	68	26

Another laboratory test which appeared to be of distinct value, was the spinal fluid examination. In all the patients with cerebral involvement there was a moderate increase in the cells, most of which were mononuclears, and definite increase in the albumin and globulin.

This group of cases was particularly interesting from a therapeutic standpoint. Quinine was used in cases 1 and 2 while patients 4, 5, 6, 7 and 8 were treated with atabrine, which is an alkyl amino-acridine derivative. Patient 3 was treated with both quinine and atabrine.

In recent years atabrine, which is a synthetic compound has been used rather extensively in tropical countries, apparently with very favorable results. There is an extensive literature on the subject, especially by German and British workers. We were particularly impressed with the favorable reports of Cordes and de la Torre,¹⁹ Green,²⁰ Hoops,²¹ Thonnard-Neumann and LeDou, ²² and Russell.²³ The only report on its intravenous use was by Mayer²⁴ in 1933.

In our series, atabrine was given by mouth only to patients 4, 5 and 6. As commented on previously, the response to this form of therapy was very prompt. Within twenty-four to forty-eight hours the temperature dropped to normal, and within four days the blood smears failed to show schizonts.

We administered this drug intravenously to three patients. In case 3 the atabrine was used after the patient apparently failed to respond to the intravenous use of quinine. There was rapid improvement after the use of atabrine. Of course it is difficult to decide whether or not the quinine was also a factor in this patient's recovery. It is to be noted that atabrine failed to destroy the estivo-autumnal gametocytes. Cases 7 and 8 failed to respond to intensive intravenous atabrine therapy. Of course patients with cerebral malaria as a rule, fail to respond to any therapeutic measure. The treatment of the pernicious form of the disease certainly merits further study.

We observed no untoward results from the use of atabrine, with the exception of a slight yellowish discoloration of the skin in one instance. This, however, cleared up within a week. Furthermore, the drug is not unpleasant to take and is not depressing.

Of course we are not prepared to draw definite conclusions in regard to the value of atabrine in malaria from so small a series of cases. It is our impression, however, that this drug is a valuable adjunct to quinine and in our opinion deserves further trial.

50 West Ninety-Sixth Street

UNDULANT FEVER DUE TO BRUCELLA OF THE PORCINE TYPE— BRUCELLA SUIIS

REPORT OF A MILK-BORNE EPIDEMIC

C. P. BEATTIE, MB, CHB

Fellow appointed by the Medical Research Council of Great Britain
under a grant from the Rockefeller Foundation

SEIMA, CURRIE, MIDLOTHIAN, SCOTLAND

AND

RAYMOND M. RICE, MD

COUNCIL BLUFFS, IOWA

Through the work of Hardy and his associates,¹ undulant fever is probably as well recognized in Iowa as in any other state. Yet, prior to 1933, only four cases of the disease were reported from the town of Council Bluffs with a population of 42,000. One of these cases occurred in 1929 and three in 1932, the last of the patients being taken ill, Nov. 7, 1932. Moreover, two of the four patients came to Council Bluffs for diagnosis.

During the months of February, March and April 1933 the disease appeared in epidemic form. In all, thirty persons were involved and of those twenty-seven were known to obtain their milk from one dairyman, who supplied approximately eighty households with raw milk. One other patient obtained milk from a grocery of which part of the milk supply came from the suspected dairy.

None of these patients were known to have contact with animals or to handle raw meat.

The clinical histories and symptoms of the patients did not differ materially from those given in previous descriptions of the disease. In some cases, however, the patients looked more seriously ill than is generally found in infections with *Brucella abortus* (the type of organism responsible for contagious abortion in cattle). From their appearance alone they gave rise to the suspicion that the infection was with the porcine type (*Brucella suis*).

The histories of the patients and the treatment used are given in brief in the accompanying table.

We do not consider that any estimate of the efficacy of the various methods of treatment used can be made on the small number of cases given here. Undulant fever is notoriously uncertain in its duration. Only by collecting and comparing a large number of cases treated by different agents will an estimate of their relative value be attained. It is in the hope that we may be of assistance in this object that we record the methods of treatment used in this epidemic.

May 4, 1933, twelve of the patients were visited and blood was taken for culture. The method used was that practiced in the Iowa State Hygienic Laboratories.^{2b} The cultures were incubated in Council Bluffs overnight and taken to the laboratory at Iowa City the next day. Four of these cultures proved positive. The dates on which a growth of *Brucella* was obtained will be found in the table of cases.

In every instance subcultures made from the original positive broth cultures on liver infusion agar yielded a vigorous growth of *Brucella* within forty-eight hours under normal atmospheric conditions.

In addition to these cultures, a culture in litmus milk (J. K.) was received, May 4, from Dr. A. A. Johnson, Council Bluffs. In direct smears from this culture he considered that he could see *Brucella*. On arrival at the laboratory this culture was transferred to liver infusion agar. It gave a vigorous growth of *Brucella* under normal atmospheric conditions in twenty-four hours. Two guinea-pigs were inoculated intramuscularly with the original milk culture. One of these died seventeen days later. At autopsy it showed lesions typical of *Brucella* infection, and the organism was found in cultures from the liver and spleen. The other guinea-pig of the pair was killed after fifty-six days and again showed lesions typical of *Brucella* infection. The organism was recovered from the spleen.

A further culture (H. P.) in liver infusion broth was taken, May 22. From this a growth of *Brucella* was obtained, May 29.

The rapid and vigorous growth of *Brucella* from these cultures under ordinary atmospheric conditions suggested the porcine type. Differentiation by the dye plate and hydrogen sulphide production methods of Huddleson² confirmed this.

Thus in blood cultures from fourteen of the patients a growth of *Brucella suis* was obtained in six.

As twenty-seven of the patients had obtained their milk from the one dairy (here designated as S), the evidence seemed to point strongly to this being the source of infection.

It was found that the dairyman had a herd of twenty cows and one bull. Inquiries into a history of contagious abortion gave essentially negative results. Eight years previously the disease had been present in the

herd and the cattle had been vaccinated with a killed vaccine. Of the animals then involved none remained in the herd at the time of the inquiry. Since that time there had been no contagious abortion in the herd. One animal had indeed, aborted during the previous year but the abortion was early in pregnancy and might well have been of traumatic origin. Another cow was said to be difficult to get in calf.

There were no hogs on the farm.

Agglutination tests carried out on the blood serum of the animals showed six to be definite reactors and two to be suspicious.

May 2, milk samples were obtained from the four reacting animals still remaining in the herd. On arrival at the laboratory the gravity cream was removed and agglutination tests were performed on the whey. One sample gave a positive agglutination test to a titer of 1:500 by Huddleson's rapid method.³ The cream from this milk was inoculated in 2 cc amounts into each of a pair of guinea-pigs. One of these animals died fifteen days after inoculation and at autopsy was found to have enlargement of the lymphatic glands in the region of inoculation. Apart from postmortem changes there was no other gross pathologic change. Cultures were made from the lymph glands and spleen, and a growth of *Brucella suis* resulted.⁴ The other guinea-pig, killed after fifty-eight days, showed lesions typical of *Brucella* infection. Culture was again positive.

It was found that the recent additions to the herd consisted of five animals. All had been purchased at the same farm (T) and were bought in calf. Three were obtained one year before and two four months before the onset of the epidemic of undulant fever. At the time of the investigation, four of these animals remained. They were all reactors and it was from one of these that the milk was obtained which was proved to contain *Brucella suis*.

The farm T was visited and there it was learned that two years before the farmer had bought some hogs in the hope of having a good yield of young pigs. Instead all his sows aborted. At this time there was no contagious abortion among the cattle but it had been present one year before.

The herd at farm T consisted of ten animals. Of these, six proved to be definite reactors and two suspicious reactors to the agglutination test for contagious abortion. By the inoculation of cream samples into guinea-pigs three of these cows were shown to be excreting the organism in their milk. The organism isolated from the inoculated guinea-pig proved, however, to be *Brucella abortus*.

The sale of milk from dairy S was stopped, April 17. The last patient to contract undulant fever in the epidemic took ill thirteen days later. Since that time till the date of writing (June 26) there has been only one further case in Council Bluffs, a patient who became ill on June 15.

COMMENT

This epidemic involved thirty persons. Of these, twenty-seven were known to have obtained their milk from one dairy. Inquiry failed to reveal any other source of infection and the last epidemic case occurred thirteen days after the sale of milk from the suspected dairy was stopped.

In blood cultures from fourteen patient *Brucella suis* was obtained in six instances. No other type of

Brucella was obtained. Among the cows remaining at the dairy, only one was found to be shedding *Brucella* in her milk. The organism was again *Brucella suis*.

It would therefore appear justifiable to assume that this was a milk-borne epidemic of undulant fever due to *Brucella suis*.

It has long been known that cattle may be experimentally infected with the porcine variety of *Brucella* and that the organism may settle in the mammary gland.⁵

Whether under natural conditions cattle may become infected with *Brucella suis* has been more in doubt.

Schroeder and Cotton⁶ failed to produce infection in cattle by feeding and cohabitation experiments. Graham and Thorp⁷ found that a small percentage of previously nonreacting cattle during twenty-six months' exposure to reacting sows and to the premises of reacting sows gave a temporary positive agglutination test for Bang's disease.

Cohabitation and feeding experiments do not, then, give very definite evidence of the likelihood of cattle becoming infected with *Brucella suis* under natural conditions. More definite evidence that this is possible is to be found in the work of Huddleson,^{2b} who out of ninety-six strains of *Brucella* isolated from bovine sources found eight to be of porcine type, in the work of Plastring and McAlpine,⁷ who out of sixty found eight porcine type and in the work of Gilman and Milks,⁸ who found four out of 117 strains isolated from cow's milk to be of porcine type.

With the exception of two cases reported by Carpenter and Merriam,⁹ no outbreaks of undulant fever due to cow's milk appear to have been reported in which the porcine variety of *Brucella* was isolated from both the milk and the patient.

Cases due to milk infected with the bovine variety of *Brucella* are common, but, none the less, there are few when compared with the amount of infected raw milk that is consumed. Traum¹⁰ estimates that approximately 20 per cent of the cattle in the United States are infected and that from 6 to 10 per cent are excreting *Brucella* in their milk. Carpenter and Boak¹¹ estimate the incidence of infection in cattle at from 15 to 20 per cent.

Milk-borne infections with the bovine variety are as a rule, scattered and rarely do more than four or five cases occur on one milk route. Exceptional is the epidemic reported by Farbar and Mathews,¹² in which twenty cases on a college campus were attributed to milk from a herd of twenty-three cows.

This disparity between the opportunity for human infection and the actual occurrence of illness has led to the belief that the bovine variety of *Brucella* is of low virulence for man. Wilcox¹³ considers that the danger of infection is relatively small when milk is used containing the bovine variety in considerable dilution.

⁴ Dr. I. F. Huddleson kindly checked the typing of this organism and of the isolated from the patients.

It would appear probable that mild or subclinical infection with *Brucella abortus* (bovine type) is more common than are active infections. Jordan in 1931th in a community of persons drinking large quantities of raw milk from an infected herd, found 8 per cent to have agglutinins to a titer of 1:20 or more and 35 per cent to a titer of 1:10 or more. From one of the members of this community, a man with no symptoms of undulant fever, *Brucella abortus* was found in cultures

from the blood. One of us (C. P. B.) in 1933 tested 197 persons in the same community and found that 6.6 per cent had agglutinins on a titer of 1:20 or more. On 193 of these persons an intradermal test was performed, a dose of 0.1 cc of a killed *Brucella* culture standardized to approximately 6 million organisms per cubic centimeter being used, 20.8 per cent gave a definitely positive reaction. None had clinical symptoms of undulant fever.

Observations in Thirty Cases of Undulant Fever

Cu. c*	Age	Sex	Date of Onset	Duration of Illness	Severity of Illness	Signs and Symptoms	Treatment	Amount of Milk Consumed Daily	Agglutination Titer	Blood Culture	Source of Milk
1 V. M.	14	♀	February	12 weeks	Moderate	Intermittent temperature chills headache 3 bouts of fever each 1 week in duration	Symptomatic	2 3 glasses	1:1280 3/20/33	Positive 5/26/33	Grocery many sources
2 M. H.	5	♀	Feb. 7	12 weeks	Moderate	Chills fever sweats	Symptomatic	1 quart	1:2560 3/14/33	Not done	S dairy
3 R. C. (A)	18	♂	Feb. 11 (elreu)	14 weeks	Moderate	Intermittent attacks of fever chills sweat joint pains	Symptomatic	Coffee and cereals only	1:640 4/23/33	Negative 5/13/33	S dairy
4 S. K. B. (B)†	42	♂	Feb. 23	23 days	Severe	Elevated temperature headache general malaise	Autogenous blood serum well 2 weeks after treatment begun	2 quarts	1:640 4/11/33	Contaminated no <i>Brucella</i>	S dairy
5 M. T. L.	40	♂	February	6 weeks	Severe	Chills fever sweats joint pains	Intravenous neutral acriflavine 1 cc 5 doses of 10 cc temperature normal 2 weeks after first dose	Coffee and cereals only	1:640 5/3/33	Not done	S dairy
6 Mrs. I. O. (A)	44	♀	March 1	12 weeks	Moderate	Malaise night sweats aching	Symptomatic	Coffee and cereals only	1:1280 4/26/33	Contaminated no <i>Brucella</i> 5/13/33	S dairy
7 H. P.	7	♂	March 1	12 weeks	Moderate	Headaches anorexia fever sweats	Symptomatic	3 4 glasses	1:640 5/6/33	Positive 5/29/33	S dairy

A B C D and F indicate that the patients were of the same family.
¹ The autogenous blood serum used in these cases was prepared by defibrinating blood and inactivating it at 56 C. In each case six doses were given at five day intervals starting with 0.1 cc and increasing by 0.1 cc for each dose.
² Patients were visited on May 4, 1933. Two other members of the household Mrs. O. L. A. and D. A. were then ill in bed with undulant fever. M. A. and O. F. A. had not taken to bed but complained of chills and malaise. O. F. A. subsequently had to take to bed.
³ O'Neil goat serum is an immune serum prepared by Dr. A. E. O'Neil of Cincinnati (Ohio State M. J. 20:48 [July] 1932) by inoculating goats with killed detoxified cultures of *Brucella*.

Dooley¹⁴ records an epidemic of subclinical infection in 7 boys boarding school, and Johns, Campbell and Tennant¹⁵ report the results of their investigation in a hospital for epileptic patients whose milk came from an infected herd. Of the group of 100 that they studied 41 per cent gave agglutination in titers of 1:10 and over and 45 per cent reacted positively to an intradermal test. By careful physical examination and temperature records 22 per cent were found to be mild ambulatory crises of undulant fever. Welch

and Mickle¹⁶ also bring forward evidence of the existence of subclinical *Brucella* infection.

The greater virulence of *Brucella suis* for experimental animals has been frequently demonstrated.¹⁷

Morales-Otero,¹⁸ by feeding experiments on human volunteers, showed the greater virulence for man of the porcine strain. These results are borne out by the observations of many workers in the United States.

¹⁴ Dooley, Parker. Undulant Fever. Arch. Int. Med. 50: 373-379 (Sept.) 1932.

¹⁵ Johns, E. P., Campbell, F. J. H. and Tennant, C. S. Canad. M. A. J. 27: 490-492 (Nov.) 1932.

that in packing houses a much higher proportion of the men employed in handling hog carcasses contract undulant fever than those handling cattle or sheep carcasses.

One would then expect a greater number of cases of active illness to be associated with a milk supply infected with *Brucella suis* than with one infected with *Brucella abortus*. In the epidemic here reported, this expectation was realized. In one fourth of the households supplied by dairy S, one or more cases of undulant fever developed.

At this stage no additional argument should be needed for the pasteurization of milk. If one is wanted, it will be found in the possibility of milk containing *Brucella suis*.

SUMMARY

1 In a milk-borne epidemic of undulant fever thirty cases occurred. Of these patients, twenty-seven obtained their milk from the same dairy.

2 The dairy, from a herd of twenty cows, supplied approximately eighty households, in eighteen of these, cases of undulant fever developed.

3 *Brucella suis* was obtained in blood culture from six of fourteen patients and from the milk of one of the cows in the herd.

4 The epidemic ceased thirteen days after the stoppage of the sale of milk from the dairy.

5 There is a greater virulence of *Brucella suis* than of *Brucella abortus*. The possibility of milk containing *Brucella suis* must be considered.

Clinical Notes, Suggestions and New Instruments

INFLUENZAL MENINGITIS REPORT OF A CASE WITH COMPLETE RECOVERY

BENJAMIN D. RITTENBERG, M.D., PHILADELPHIA

The reasons for reporting this case of influenzal meningitis are twofold: first, such cases are comparatively rare and, second, the patient made a complete recovery.

REPORT OF CASE

H. Z., a girl, aged 8 years, on the morning of February 8 complained of a headache, which had been present since her evening meal the night before. A tentative diagnosis of a gastric upset was made and treatment prescribed. The following day, about thirty-six hours after the onset, after a careful examination, the only manifestation that could be elicited was a suggestion of nuchal rigidity. She had vomited that morning. A spinal puncture revealed cloudy fluid under a great deal of pressure with a cell count of 1,300. The patient was then sent to the St. Agnes Hospital.

The past medical and family histories contained nothing of importance in relation to the illness. On examination the child was mentally alert. There was a definite Brudzinski's sign and a positive Kernig's. The reflexes were slightly exaggerated. The pupils were equal and reacted to light and in accommodation. The remainder of the examination was negative.

On admission, the patient's temperature was 103.4 F, pulse 132, respiration rate 34. Having received three toxin-antitoxin injections five years previously, she was desensitized by the injection of 0.1 cc of antimeningococcus serum hypodermically, the dosage being increased 0.1 cc every half hour until 5 cc was used; she was then given 30 cc of antimeningococcus serum intravenously. Another spinal puncture was done and 15 cc of antimeningococcus serum was introduced. The spinal fluid was cloudy, the cell count was 370, with a differential of polymorphonuclear cells 88 per cent, and lymphocytes 12 per

cent. Examination of the sugar was negative, globulin was 4+, and the smear and culture were also negative. The blood count was as follows: red blood cells, 3,840,000, white blood cells, 25,200, hemoglobin, 80 per cent, polymorphonuclear cells, 76 per cent. The urine was neutral with a specific gravity of 1.038, there was a trace of albumin and an occasional white blood cell. Within the following forty-eight hours she was given 30 cc of antimeningococcus serum intravenously, and, after as much spinal fluid as possible was withdrawn, 15 cc of the same serum was introduced intrathecally at intervals of eight hours. Between 25 and 40 cc of spinal fluid was removed at each puncture to lower the pressure to normal. These specimens showed a cell count varying between 94 and 438, with a preponderance of polymorphonuclear leukocytes, examination of the sugar was negative, globulin was 4+, and the chlorides varied between 580 and 680 mg per hundred cubic centimeters. The Levinson test was negative, and no acid-fast bacilli were found. On the second day the spinal fluid showed a growth of gram-negative bacilli, which at first were mistaken for diplococci but were later proved to be influenzal bacilli. During this forty-eight hour period the temperature varied between 100.2 and 105 F, the pulse between 100 and 136, and the respirations between 24 and 38. The patient complained of severe headache. The nuchal rigidity was always aggravated after the serum was introduced into the spine.

On the third day of admission several smears of the spinal fluid revealed gram-negative bacilli similar to those found in the positive culture the day before, and a positive diagnosis of influenzal meningitis was made by Dr. John Kolmer. It was then decided that anti-influenzal serum should be used. After the spine was drained 15 cc of anti-influenzal serum mixed with from 3 to 5 cc of fresh complement was introduced intrathecally every eighth hour. This was continued for forty-eight hours. During this period the cell count varied between 101 and 220. Examination of the sugar was negative and the globulin was reduced to 2+. All smears were negative. The temperature varied between 100.4 and 103.2, and the reflexes were almost entirely gone. The nuchal rigidity was very marked at this time, the patient acquiring the position of opisthotonos, but there was no evidence of paralysis or mental disturbance. The serum was now given every twelfth hour. At times the spinal fluid was under greater pressure than at others, remaining cloudy, but the sugar was beginning to return. The globulin was 2+, and the chlorides varied between 540 and 680 mg per hundred cubic centimeters. The twelve hour treatment was continued for two days, after which time an anti-influenzal serum of another biological house was used. Although it was realized that the patient was improving clinically and the spinal fluid was approaching normal, the pressure was diminished, sugar was returning, and globulin dropped to 2+, the change of serum was made because several smears still showed gram-negative bacilli, and it was felt that the new serum was probably made from different strains of influenzal bacilli. This serum was given every twelfth hour for three days and then once daily. The globulin gradually decreased and sugar slowly returned. Several smears still showed gram-negative bacilli. The temperature gradually came down as did the pulse and respiration rates. The last positive smear was reported February 21, the serum being discontinued three days later. However, the spine was tapped every other day until February 27, each smear being reported negative. Sugar was normal but there was still a slight increase in the cell count and globulin. The increase in the cells and globulin was due to the irritation of intrathecal medication. During the course of the illness, almost 750 cc of spinal fluid had been removed and 565 cc of serum introduced into the spine.

February 15, six days after admission, an urticaria developed, which was controlled by epinephrine hypodermically and calcium gluconate by mouth. The urticaria was probably due to the antimeningococcus serum given intravenously.

The temperature reached normal February 24 and remained so until the time of her discharge from the hospital, March 9, twenty-eight days from the time she had been admitted. The spinal fluid was entirely normal, and at present (six months following her illness) she is enjoying perfect health.

1 This serum was procured through the courtesy of Dr. L. J. Wenger.

ETIOLOGY

Influenzal meningitis belongs to the group of acute purulent meningitides. It is caused by the influenza bacillus or bacillus of Pfeiffer. There are numerous strains of the organism, which explains the difficulty at times of recognizing it microscopically. It is a gram-negative rod varying in size and shape from small diplococci to short or long bacilli staining at the poles.

Influenzal meningitis most commonly occurs in children under 2 years of age, usually in the fall and early winter. Curiously enough it rarely occurs during an epidemic of influenza but this may be due to the fact that the strains of the bacilli that cause meningitis are not prevalent during an epidemic. It may occur as a primary disease as the case here cited or it may be secondary to an influenzal infection elsewhere. Neal² is of the opinion that most cases are secondary and believes that, if a careful inquiry into the history is made an otitis media or sinus infection can be found.

The symptomatology of this disease is not unlike that of other purulent forms of meningitis.

DIAGNOSIS

The diagnosis rests on the changes in the spinal fluid. The spinal fluid is usually under increased pressure and shows the characteristics of an inflammatory exudate. The cells are increased with a preponderance of polymorphonuclear leukocytes, albumin and globulin are increased, and sugar is diminished or absent. It is important to mention not only that the cells should be counted promptly after the spinal puncture but that a tube of the fluid should be centrifuged at once, a smear made and stained immediately, to avoid not only contamination but also autolysis of the organisms. The interpretation of stained smears is more important than culture of the fluid, and since it is difficult to grow the bacilli, it would take several days to make a diagnosis. The frequent study of the smears aids in the diagnosis and in determining whether or not the spinal fluid is bacteria free. The latter is a guide as to whether or not the serum should be continued in the treatment of the case.

PROGNOSIS

The mortality is extremely high. Griffith and Mitchell³ and Morse⁴ state that they have never seen a patient recover. Bloom⁵ collected reports of 302 cases, with a mortality of 92 per cent. Jenks and Radbill⁶ reported a mortality of 98 per cent in eighty-seven cases. The small percentage of patients who do survive are usually crippled because of various palsies or are left mentally retarded from a hydrocephalus.

TREATMENT

The most important factor in the treatment of this disease is an early diagnosis. Until the causative organism is found each case of meningitis should be treated as that of meningococcic meningitis. No harm can be done if the canal is drained and meningococcus serum is introduced. If Pfeiffer's bacillus is found immediate treatment with the anti-influenzal serum should be instituted.

The serum was obtained after five months' injection of a horse with twelve selected strains of influenza bacilli, recently isolated from cases of influenzal meningitis and acute respiratory infections. Selection of strains for injection of horses was determined by the character of colony (smooth) by the degree of antigenicity and by the polyvalence. Selection of serum for therapeutic uses was determined by its agglutination titer against the strains of influenza bacilli.

In the treatment the introduction of 15 cc of the serum with 5 cc of fresh complement is recommended after as much spinal fluid as possible has been removed. The latter is used because there is no complement in the spinal fluid in influenzal

meningitis.⁸ Fresh human serum in combination with anti-meningitis serum, however, definitely increases opsonic activity.⁹ It is best procured from either parent by removing about an ounce of blood several hours before it is used and icing it at once. A clot will form, and the serum can be removed easily with a sterile glass pipet. This treatment should be repeated every eighth hour for two or three days, then every twelfth hour for two or three days and finally, once a day. If there is blockage in the canal, use of either the fontanel, if open or the cisterna may be resorted to. If an infection of the skin develops owing to the numerous punctures, another site should be selected to avoid introducing an infection into the canal. If there is no improvement within two or three days, a change of serum is advisable as the biologic houses do not employ the same strains of bacilli in the preparation of the serum. Daily injections of the serum should be continued until three successive negative smears are found. Should the bacilli return after several negative days, the daily injections should be repeated.

Absolute rest in bed with a soft diet and plenty of fluids are essential. The secondary anemia, which usually accompanies or follows the illness, should be treated during the convalescence with iron and arsenic by mouth and by injection, if necessary.

CONCLUSIONS

Since the mortality of influenzal meningitis is very high, an early diagnosis, with frequent spinal drainage and intrathecal treatment with specific serum, is the only means at present by which the mortality and morbidity may be reduced.

5400 West Arlington Street

TORSION OF THE NORMAL OVARY

CASE OF REOCCURRENCE OF A RARE PATHOLOGIC CONDITION

CHARLES BARON, M.D., COVINGTON, KY.

The annals of American medicine and surgery contain many rare reports, but it is seldom that the rarity occurs in the same individual on two different occasions. In a previous paper¹ a report was given of the torsion of a normal ovary and its tube with rupture of the ovary. With an addendum² to the first paper twenty-six cases of torsion of the normal ovary with and without the normal fallopian tube were gathered from all the available literature. However in no instance had the identical condition reoccurred. A perusal of the available literature since the previous papers also supplies no such double occurrence. The nearest like double occurrence was reported by Mankad.³ In this case a right cystic ovary was found twisted and on inspection of the left ovary it was found to be normal but twisted, buried in adhesions. In the present case, two years and three months elapsed between the two identical surgical conditions.

REPORT OF CASE

W. S., a girl May 14, 1931, when 7 years of age was operated on for acute appendicitis with a mild peritonitis as the provisional preoperative diagnosis. When the peritoneal cavity was entered a mass shaped like a kidney, attached to a pedicle about 3 cm long was found in the pelvic midline. On its medial side could be seen the right fallopian tube and on its lateral side could be seen a rent about 1.5 cm long, with no blood issuing from it. The mass and its tube as well as the appendix was removed. Before the abdomen was closed, examination of the left ovary and tube revealed them to be normal in size and consistency. The pathologic diagnosis was torsion of the right normal ovary and tube with rupture of the ovary. After a stormy convalescence for the first three days the patient made an uneventful recovery.¹

⁷ Wenger L. J. Personal communication to the author.

Following this operation, she had brief periods of pain in the region of the left brim of the pelvis. Laxatives relieved it. A slight constipation was always relieved by laxatives. Aug 17, 1933, at the age of 9, about two years and three months following the first operation, she woke up with pain in the left lower quadrant. An enema gave complete relief. Two days later she awoke at 6 a. m. with pain in the same region. An enema and laxatives failed to relieve her. Three or four enemas were given during the day and, no relief being obtained, codeine was given. During the day she began to vomit, four times in all. The next morning, the fourth day, enemas and oil failed to relieve her and she was then brought to the hospital. When she entered, she was experiencing attacks of pain at hourly, one and one-half hourly and two hourly intervals. She began to vomit again. The abdomen was slightly distended. Abdominal palpation revealed no rigidity but there was distinct tenderness in the right lower quadrant just above the pelvic brim. A rectal examination revealed the presence of a mass in the midline that could not be identified as any definite viscera or as a foreign mass.

Roentgen examination revealed a considerable accumulation of gas in the colon but no definite evidence of obstruction. The kidney outlines were not made out. The entire abdomen was opaque, accumulation of fluid being present.

The preoperative diagnosis of torsion of the ovary was made for the following reasons: 1 A mass was felt in the midline, too large to be the uterus. 2 The appendix had previously been removed. 3 Timing of the pains ruled out obstruction or intussusception. 4 There had been a previous torsion of the left ovary.

Under ethyl chloride and ether anesthesia an abdominal incision was made in the median line. There was no free fluid in the peritoneal cavity. Over the uterus in the midline was found a kidney-shaped, dark red ovary twisted one and one-half times to the right, with a pedicle about 0.5 cm long. After the pedicle had been clamped with difficulty, tied and cut the ovary and tube were removed. The abdomen was closed with out drainage. The patient stayed in the hospital eleven days and made an uneventful recovery.

Pathologic examination showed the ovary and oviduct to be a deep purplish red. On section the serosa and the muscularis and the mucosa of the oviduct were a uniform purplish red and the tissue was rather friable. The cut surface was covered with blood. The attached ovary was kidney shaped and measured $3\frac{1}{2}$ inches (9 cm) in length. The cut surface was a uniform deep purplish red and was covered with blood. Throughout the ovary there were multiple follicles, normal in size but filled with blood. The ovarian tissue was more friable than normal. Microscopic examination of the ovary and oviduct revealed massive hemorrhage into the tissues which was so extensive that the normal structures could not be identified. The pathologic diagnosis was hemorrhagic infarction of the ovary and oviduct, the clinical diagnosis, torsion of the left ovary and tube.

COMMENT

It is interesting to recall¹ that anatomic anomalies were considered to be the chief predisposing factors in producing torsion of the ovary. It had been felt that 'our patient had originally a large ovary, etiologic factor stressed by Norris⁴ and Auvray.⁵ Second, the ovary had an abnormally large pedicle that had formed when the large ovary had drawn away from the broad ligament also suggested by these two men. Third, with these factors already present, her straining at stool for the past year was the needed factor to bring about repeated pelvic congestion and bring about the torsion as stressed by Rost.⁶ Having been able in a most fortunate manner to see the second and remaining tube and ovary in situ at the first operation and having seen no evidence of anatomic anomalies I am forced to the conclusion that anatomic anomalies are probably not the chief factors necessary toward torsion of the uterine adnexa. This can safely be said for the second torsion but cannot be

said for the first since the latter was not seen beforehand. In addition, the pedicle was considerably longer the first time. Because of the obscurity of a definite clinical picture denoting a bowel involvement, coupled with the palpation of a mass near the uterus and because of a past history of a like preceding pathologic condition, a correct diagnosis of torsion of the ovary was made preoperatively.

CONCLUSIONS

1 A case of torsion of the normal ovary and tube was observed in which the same condition occurred twice, involving one ovary and its tube and then the other, in a space of two years and three months. It is believed that this is the first case on record in which this rare pathologic condition occurred in the same individual twice.

2 It is believed that this is the first time that a positive diagnosis of torsion of the normal ovary has been made preoperatively.

3 In the differential diagnosis of abdominal pain in young girls torsion of the uterine adnexa must be considered.

4 Factors other than anatomic anomalies must be considered in the predisposing causes toward torsion of the normal uterine adnexa.

A COMBINED NEEDLE ADAPTER AND THERMOMETER FOR INTRAVENOUS INFUSIONS

PAUL TITUS, M.D., PITTSBURGH

A thermometer with a limited range of from 90 to 120 Fahrenheit which is sufficient for intravenous infusions of various sorts has been inserted within the lumen of an enlarged but otherwise ordinary glass adapter the tip of which is ground for intravenous needles with a standard Luer hub. This is a spirit thermometer with a colored (red) fluid and thus is easily read.

Glass adapters for the attachment of the needles are used for practically all intravenous injections. The use of the usual large infusion thermometers involves the addition of an extra breakable part and an extra piece of rubber tubing. Con

Combined needle adapter and thermometer for intravenous infusions

sequently the combination of these two parts in one makes for simplicity, at the same time allowing for more accurate information regarding the actual temperature of an intravenous infusion as the thermometer is located near to the point of entry of the fluid into the vein.

When an injection is begun blood should not be allowed to "back up" into the infusion thermometer, as it may be held by capillary attraction and the tube may therefore be difficult to clean later. When this does occur, prolonged immersion in a small amount of hydrogen dioxide alternating with a weak solution of nitric acid, will ordinarily clean the tube.

These infusion thermometers are relatively inexpensive and are made by Becton, Dickinson and Company of Rutherford, N. J.

*Special Article*TYPHOID IN THE LARGE CITIES OF THE
UNITED STATES IN 1933

TWENTY-SECOND ANNUAL REPORT

This report deals with the same ninety-three cities that have been discussed in the corresponding articles covering the years 1930, 1931 and 1932. The number of deaths from typhoid during 1933 in each city (except Scranton, as explained in a note to table 2) has been supplied by the respective health department. As the United States Bureau of the Census has found its usual method of computing the midyear populations of the large cities unsatisfactory for 1933 on account of the effects on such populations of the present economic conditions and has therefore made no estimates as of July 1, 1933, the rates in the present article are based on the estimates of the Census Bureau for July 1, 1932.

The problem of including in the rates for each city the typhoid deaths of nonresidents is as conspicuous as it has been for some years. In thirty-one of the

ninety-three cities we are informed that one third or more of the typhoid deaths were in nonresidents, in seven of these thirty-one cities all the typhoid deaths were in nonresidents. These are indicated in table 9, which should be referred to also in studying tables 1-8.

Particulars as to the data that are unavailable for certain cities (noted in tables 2-8 as "incomplete data") are given in the report covering the year 1932 and in the footnotes to these tables in all earlier articles.

The large New England cities again make an excellent record (table 1). Three cities (Fall River, Lynn and Waterbury) had no typhoid deaths within their borders for the third consecutive year. Two other cities in this group (New Haven and Worcester) report that the only typhoid deaths occurring in 1933 were in nonresidents. In the past four years (1930-1933) all but five (Boston, Hartford, Springfield, Lowell and Providence) of the New England cities

have had at least one year of complete freedom from typhoid mortality. Perhaps the most remarkable record in this group is that of Boston, which registers the very low rate of 0.2, the lowest in its history and one of the lowest ever recorded by an American city with more than 500,000 population. At that, it is stated that one third or more of the reported typhoid deaths were in nonresidents. The group as a whole reports a new low average for 1933, making it practically certain that the

† Typhoid deaths for Scranton furnished by Pennsylvania Department of Health, Harrisburg.

New England cities, with a population of more than 2,500,000, will not average one typhoid death per hundred thousand inhabitants in the current five year period. This group of cities is excelled only by those of the East North Central states (table 4).

The cities in the middle Atlantic states show even greater improvement in 1933 than in the preceding year and record an average rate of less than one per hundred thousand for the second year in succession (table 2). Five cities in this group (Elizabeth, Paterson, Reading, Utica and Yonkers) report the complete absence of typhoid deaths during the year 1933. Elizabeth for the second year in succession. Utica has had

† Incomplete data.

a perfect record in three out of the past four years. Pittsburgh, which twenty-five years ago lost annually from typhoid about one of its citizens in every 1,500 of population, now reports but a single typhoid death in a population of approximately 700,000. Both Philadelphia and New York now have typhoid rates under 1 per hundred thousand. Camden, which still has relatively a technically high rate, reports that all the deaths were in nonresidents so that there is evidently some missionary work to be done in the environs of that city. Scranton, which brings up the foot of the list, seems to have had more typhoid than for some years.

The preceding articles in this series were published in THE JOURNAL May 31, 1913, p. 1702; May 9, 1914, p. 1473; April 17, 1915, p. 1322; April 22, 1916, p. 1305; March 17, 1917, p. 845; March 16, 1918, p. 777; April 5, 1919, p. 997; March 6, 1920, p. 672; March 26, 1921, p. 860; March 25, 1922, p. 890; March 10, 1923, p. 691; Feb. 2, 1924, p. 389; March 14, 1925, p. 813; March 27, 1926, p. 948; April 9, 1927, p. 1148; May 19, 1928, p. 1624; May 18, 1929, p. 1674; May 17, 1930, p. 1574; May 9, 1931, p. 1576; April 30, 1932, p. 1550; and May 13, 1933, p. 1491.

1. The problem of the nonresident has been discussed at some length in our previous reports, for example, J. A. M. A. 100, 1491 (May 13), 1933, and 9S, 1:550 (April 30), 1932.

The cities in the South Atlantic states have not done quite so well as a group. Wilmington, Miami, Washington and Norfolk all showing increases as compared with 1932 (table 3). Miami and Norfolk, however, report that one third or more of typhoid deaths were in nonresidents. Baltimore in this group makes a particularly fine showing, reporting the lowest rate ever recorded in that city. Atlanta also shows remarkable

improvement although it has still far to go before it can rival Baltimore. Many of the cities in this group have, as is well known, a large Negro population and it used to be supposed that the high typhoid rates of these and other Southern cities were due in large part to the excessive mortality from typhoid among the Negro populations. Analyses of the typhoid death rates in several Southern states, however, have shown that in many localities the white typhoid mortality is as high as the typhoid mortality among Negroes, and in some localities even higher. Racial distribution of the population, therefore, can no longer serve as an explanation for the relatively high typhoid mortality in the cities in the South Atlantic and East South Central states. The remarkable improvement in Baltimore in the past two decades should serve as a stimulus to the other cities in this group. Is there any reason why Washington should not be able to do as well as Baltimore? For three years it has lagged a little.

TABLE 5—Death Rates of Six Cities in East South Central States from Typhoid per Hundred Thousand of Population

Nashville	7.6	7.6	3.2	18.2	17.8	20.7	40.2	61.2

* Incomplete data

The cities of the East North Central group (table 4) again lead all other sections of the country in having the lowest typhoid average of any geographic division and increase their 1932 lead over the New England cities. Five cities in this group (Canton, Evansville, Flint, Fort Wayne and Grand Rapids) have perfect scores and Chicago, Milwaukee and Cleveland are not far behind. All but five of the eighteen cities in this division have rates less than 10, and the highest is only 23.

The six cities of the East South Central states (table 5) with a population about one-eighth as great as the eighteen cities of the East North Central division have registered a larger number of typhoid deaths in 1933 (77 East South Central, 68 East North Central) and a typhoid rate nearly ten times as high, viz., 4.91 in contrast to 0.55 (table 12). Some improvement over 1932 is, however, manifested particularly by Chattanooga and Memphis. The Nashville rate remains surprisingly high for the second year in succession. The racial analysis of Nashville typhoid for 1932, already referred to, shows that the typhoid mortality in the white population in that city was nearly double that among the Negroes. Only one other American

city on our list (New Orleans) exceeded Nashville in 1933 in its typhoid rate. Nashville, nevertheless, is showing marked improvement over the period 1916-1930, when hardly any typhoid reduction occurred (table 5).

The cities in the West North Central states (table 6) did not fare quite as well in 1933 as in 1932, five of the nine showing a typhoid increase and two a stationary rate. Kansas City, Mo., indeed recorded a typhoid mortality nearly as great as the average for 1926-1930. Since a large proportion of deaths among nonresidents is reported by this city, conditions just outside the

political boundaries evidently need looking into. Minneapolis and Omaha in this group have remarkably fine records.

The eight cities in the West South Central states (table 7) show on the average a slight increase over the preceding year, although Tulsa maintains its perfect record and El Paso shows a substantial decrease. Fort Worth and San Antonio, however, have not done

1933	93	0	7	18	19	30	16

typhoid rate in the country, as was the case in 1933 (table 12).

The cities in the Mountain and Pacific states (table 8) average slightly less than in the preceding year, but the rates range more widely. Portland and Salt Lake City report no typhoid deaths and San Francisco a rate of only 0.1. San Francisco is rivaled only by Pittsburgh in its remarkably low typhoid rate among cities of more

than 500,000 population. San Diego reports its highest rate (4.3) for a decade or more. While such a figure does not perhaps indicate an epidemic, there is evidently something that needs looking into in that

TABLE 11—Total Typhoid Rate for Seventy-Eight Cities 1910-1933*

	Population	Typhoid Deaths	Typhoid Death Rate per 100,000
1910	22,573,437	4,637	20.54
1911	23,211,341	3,900	17.02
1912	23,835,999	3,132	13.14
1913	24,457,989	3,985	13.4
1914	25,091,112	2,781	11.08
1915	25,713,846	2,434	9.47
1916	26,257,700	2,191	8.34
1917	26,860,408	2,016	7.50
1918	27,086,666†	1,874†	6.73
1919	27,735,084†	1,111†	4.15
1920	28,344,474	1,088	3.8†
1921	28,859,662	1,141	3.95
1922	29,473,746	963	3.26
1923	30,087,430	900	3.16
1924	30,701,614	904	3.07
1925	31,315,596	1,070	3.44

* Lacks data for Jacksonville and Miami.

† Data for South Bend for 1929-1930 are not available.

* Lacks data for Oklahoma City in 1929.

† Lacks data for Oklahoma City.

In 1933 for the first year since our summaries were undertaken, no city in the United States registered a typhoid mortality rate greater than 10 per hundred thousand (table 10). Sixteen of the ninety-three cities had no typhoid deaths at all in 1933, the largest number of cities yet reported with a perfect score. The American people can congratulate themselves that the improvement in typhoid mortality is still going on. This is substantiated by the figures in table 11, in which it is shown that the typhoid rate for 1933 reached the lowest point ever registered. It should be noted also

that the improvement probably is actually somewhat greater than the figures indicate, since the 1932 population estimate is used without making any allowance for possible increase. From the figures given in this table, a notable saving of life has resulted from the campaign against typhoid in the past twenty-three years. It is a little surprising, however, to find what a marked improvement is still taking place, the typhoid mortality rate in American cities of more than 100,000 population is now less than half what it was only seven years ago.

Council on Physical Therapy

THE COUNCIL ON PHYSICAL THERAPY OF THE AMERICAN MEDICAL ASSOCIATION HAS AUTHORIZED PUBLICATION OF THE FOLLOWING REPORT
H. A. CARTER, Secretary

BURDICK WATER-COOLED LAMPS ACCEPTABLE

The Burdick Corporation, Milton Wis. manufactures quartz mercury vapor arc water cooled lamps which are recommended for therapeutic use when local application of ultraviolet radiation is required. Several models were considered. They are as follows:

- Self Contained Mobile Water Cooled Unit Receptor Model
 - I W 505 for Alternating Current
 - I W 205 for Direct Current
- Suspension Casing Model Self Contained Unit
 - LW 510 for Alternating Current
 - LW 210 for Direct Current
- Suspension Casing Model Faucet Type Water Cooled Unit
 - I W 531 for Alternating Current
 - LW 231 for Direct Current
- Receptor Model Faucet Type Water Cooled Lamp
 - I W 530 for Alternating Current
 - I W 230 for Direct Current

The water-cooled unit, that is, the lamp proper consists essentially of a quartz mercury vapor arc burner surrounded by a double wall casing between the walls of which cold water circulates to cool the lamp. A small circular quartz window in the casing permits the passage of ultraviolet and visible radiation but practically eliminates the heat radiation. The quartz window looks like a small crystal drum and the hollow space is filled with highly distilled water. This distilled water does not come directly in contact with the circulating water. The radiant heat passing through the window is largely absorbed by the distilled water and transparent quartz and is conducted to the circulating water through the periphery of the quartz drum. Then the excess heat in the lamp is carried away either by water circulating in the radiator, which in turn is dissipated to the air, or by tap water circulating through the lamp from a faucet. When running an indicator shows instantly whether water is circulating. It is possible therefore to use the lamp in close approximation to the affected or injured part and to apply pressure against the soft parts to facilitate greater penetration of the ultraviolet radiation.

Burdick
Water Cooled
Lamp

All models use the same type of lamp and burner. The difference in the models depends on the accessories. The Self-Contained Mobile Water-Cooled Unit, receptor model, is provided with a cabinet which has a movable door located in the rear, thus making the unit accessible for lubrication or draining of the water system. This unit is mounted on four ball-bearing casters with solid rubber-tired wheels and can be moved about the hospital or physician's office easily.

The Suspension Casing Model Self-Contained unit is essentially the same as the previously described unit. In addition it is supplied with a special counterbalanced upright, to which the lamp is attached. The Suspension Casing Faucet Type Water-Cooled unit is essentially the same as the last mentioned unit, except that the cooling water supply is obtained from a faucet connection. The Burdick Receptor Model Faucet Type Water-

Cooled Lamp contains all the essential features of the "mobile" type, differing in that the cooling water is obtained from a faucet of the local water supply.

ELECTRICAL CHARACTERISTICS

Alternating Current

- Line voltage 105 to 120 volts (60 or 25 cycles)
- Line starting amperage 17.5 amperes
- Line operating amperage (5 amperes 220 volt line)
(7.5 amperes 115 volt line)

Operating amperage of burner 4.5 amperes

Burner voltage always kept at 55 by means of manual voltage regulator. (There is therefore no maximum or minimum burner voltage as it is kept at 55 volts.)

Direct Current

- Line voltage 105 to 120 volts
- Starting amperage 10 amperes
- Operating amperage (120 volts 4.5 amperes)
(220 volts 4.5 amperes)

Burner voltage always kept at 55 by means of manual voltage regulator.

One unit was examined in a clinic acceptable to the Council. The report of this investigation indicated that the claims made for the device were in agreement with the Official Rules of the Council on Physical Therapy. The Burdick Water-Cooled Lamps therefore are eligible for inclusion in the list of accepted devices.

Council on Pharmacy and Chemistry

NEW AND NONOFFICIAL REMEDIES

THE FOLLOWING ADDITIONAL ARTICLES HAVE BEEN ACCEPTED AS CONFORMING TO THE RULES OF THE COUNCIL ON PHARMACY AND CHEMISTRY OF THE AMERICAN MEDICAL ASSOCIATION FOR ADMISSION TO NEW AND NONOFFICIAL REMEDIES. A COPY OF THE RULES ON WHICH THE COUNCIL BASES ITS ACTION WILL BE SENT ON APPLICATION.

PAUL NICHOLAS LEECH, Secretary

DIPHTHERIA TOXOID, ALUM PRECIPITATED (REFINED)—(See THE JOURNAL, Feb. 24, 1934, p. 605, and New and Nonofficial Remedies, 1934, p. 393)

Lederle Laboratories, Inc., Pearl River, N. Y.

Refined Diphtheria Toxoid (Alum Precipitated) Lederle—Prepared from diphtheria toxin the L+ dose of which is 0.2 cc and which has been detoxified with 0.2 and 0.4 per cent solution of formaldehyde to make diphtheria toxoid. The toxoid is refined by precipitation with a 4 per cent solution of potassium aluminum sulphate washed with sterile physiological solution of sodium chloride and resuspended in the same menstruum. It is preserved with Merthiolate 1:10,000. The product is tested for antigenic potency according to the method prescribed by the National Institute of Health: guinea pigs weighing 500 Gm. given one human dose must produce at the end of six weeks at least two units of diphtheria antitoxin in each cubic centimeter of blood. Marketed in packages of one 1 cc. vial (one immunization), ten 1 cc. vials (ten immunizations) and one 10 cc. vial (ten immunizations).

MERCURIC SUCCINIMIDE (See New and Nonofficial Remedies, 1934, p. 293)

Refined Solution Mercuric Succinimide 16 grain (0.01 Gm.) 1 cc. Mercuric succinimide N. N. R. 0.01 Gm. benzyl alcohol 0.01 cc. and glycerin 0.013 Gm. in sufficient distilled water to make 1 cc.

Prepared by the Cheplin Biological Laboratories, Inc., Syracuse, N. Y. No U. S. patent or trademark.

SOLUBLE STOMACH EXTRACT-FAIRCHILD—A concentrated extract of material derived from mammalian stomach mucosa. It is marketed in vials containing approximately 3 Gm. of substance representing material derived from 100 Gm. of fresh stomach mucosa.

Actions and Uses—Soluble stomach extract-Fairchild is proposed for oral administration in the treatment of pernicious anemia.

Dosage—This is determined by the condition of the patient. Ordinarily, the contents of from three to six vials (approximately 8 to 16 Gm.) are given daily in cool fluids. The maintenance dose is determined individually for each patient.

Manufactured by Fairchild Bros. & Foster, New York. No U. S. patent or trademark.

Soluble stomach extract Fairchild is a light buff colored powder possessing the characteristic odor and taste of preparations of this type. It is almost completely soluble in cold water.

To prepare soluble stomach extract Fairchild the entire stomach mucosa is ground to a fine pulp directly into water. The resulting mixture is adjusted to a pH of 1.8, submitted to a temperature of 38°C. for a period of about six hours and then partially neutralized to a pH of 5. The resulting product is clarified by filtration and dried in vacuum at low temperature.

TRIBASIC CALCIUM PHOSPHATE (See New and Nonofficial Remedies, 1934, p 134)

Ucoline Calcium Phosphate Cocoa Wafers Each wafer contains tribasic calcium phosphate N N R 0.585 Gm (9 grains) cocoa 0.65 Gm (10 grains) powdered sugar 0.3 Gm (5 grains) starch 0.021 Gm ($\frac{1}{4}$ grain) and saccharin 4.8 mg ($\frac{1}{10}$ grain) flavored with coumarin, vanilla oil of peppermint, and salt

Prepared by Ucoline Products Company, Chicago No U S patent or trademark

REPORTS OF THE COUNCIL

THE COUNCIL HAS AUTHORIZED PUBLICATION OF THE FOLLOWING REPORT
PAUL NICHOLAS LEECH Secretary

MERCUROSTICKS NOT ACCEPTABLE FOR N N R AND CAUSTICKS, CAUSTICK APPLICATORS AND SPECIAL CAUSTICK APPLICATORS (SILVER NITRATE 75 PER CENT), CUPRICSTICKS, CUPRIC APPLICATORS AND SPECIAL CUPRIC APPLICATORS (COPPER SULPHATE 20-25 PER CENT), STYPSTICKS, STYPSTICK APPLICATORS AND SPECIAL STYPSTICK APPLICATORS (ALUM 75 PER CENT AND POTASSIUM NITRATE 25 PER CENT) OMITTED FROM N N R

Some years ago the Council accepted for inclusion in New and Nonofficial Remedies a line of "medicated sticks" for application of various medicaments manufactured by the Tappan Zee Surgical Company and marketed under the names Causticks, Caustick Applicators and Special Caustick Applicators (Silver Nitrate 75 per cent), Cupricsticks, Cupric Applicators and Special Cupric Applicators (Copper Sulphate 20.25 per cent), Stypsticks, Stypstick Applicators and Special Stypstick Applicators (Alum 75 per cent and Potassium Nitrate 25 per cent)

In 1928 the firm presented an additional medicated stick under the name "Mercurosticks" stated to bear a tip of solidified mercurochrome-H W & D. The Council held that the name was not sufficiently informative since it might be applied to any mercury preparation and the Tappan Zee Surgical Company was informed that the product would be acceptable under the name "Mercurochromesticks." The firm took no action to make the product acceptable. During the examination of the material recently sent by the firm in connection with the reconsideration of other products of its manufacture a label for "Mercurosticks" was discovered. The firm was reminded of the Council's action with regard to Mercurosticks and was asked to make a statement for the Council's information. The firm replied, in effect that it could not give up the coined name "Mercurosticks." The Council therefore declared the product unacceptable for New and Nonofficial Remedies because it is marketed under an insufficiently descriptive name.

In accordance with the Council's custom the Tappan Zee Surgical Company was informed of the Council's action but made no reply. A second letter which unfortunately lacked sufficient postage, was sent the firm and was returned endorsed with a facetious remark. Convinced that some irresponsible person had made the endorsement the Council's Secretary sent a registered letter thinking thereby to reach some responsible person in the concern. This letter was refused. Meanwhile, the Council had reaccepted the products of the firm, the acceptance of which had expired. No acknowledgment was received of the notification sent the firm of this reacceptance. Refusal of a firm to receive correspondence from the Council makes it impossible for the Council to check adequately the claims made for the firm's product.

In view therefore of the unwarranted refusal of the Tappan Zee Surgical Company to cooperate with the Council the Council concluded that continued recognition of its products is impossible. The Council therefore reaffirmed its rejection of Mercurosticks and omitted from New and Nonofficial Remedies the accepted products of the firm, namely Causticks, Caustick Applicators and Special Caustick Applicators (Silver Nitrate 75 per cent), Cupricsticks, Cupric Applicators and Special Cupric Applicators (Copper Sulphate 20.25 per cent), Stypsticks, Stypstick Applicators and Special Stypstick Applicators (Alum 75 per cent and potassium nitrate 25 per cent).

Committee on Foods

ACCEPTED FOODS

THE FOLLOWING PRODUCTS HAVE BEEN ACCEPTED BY THE COMMITTEE ON FOODS OF THE AMERICAN MEDICAL ASSOCIATION FOLLOWING ANY NECESSARY CORRECTIONS OF THE LABELS AND ADVERTISING TO CONFORM TO THE RULES AND REGULATIONS. THESE PRODUCTS ARE APPROVED FOR ADVERTISING IN THE PUBLICATIONS OF THE AMERICAN MEDICAL ASSOCIATION AND FOR GENERAL PROMULGATION TO THE PUBLIC. THEY WILL BE INCLUDED IN THE BOOK OF ACCEPTED FOODS TO BE PUBLISHED BY THE AMERICAN MEDICAL ASSOCIATION.  RAYMOND HERTWIG Secretary

FAIRWAY BRAND IODIZED TABLE SALT

Distributor—Twin City Wholesale Grocer Co., St. Paul and Minneapolis

Packer—Morton Salt Company, Chicago

Description—Table salt containing 0.023 per cent of potassium iodide, 0.1 per cent of sodium carbonate and 0.7 per cent of magnesium carbonate. Same as Morton's Iodized Salt, THE JOURNAL, Feb 18, 1933, page 499

Claims of Manufacturer—For all table and cooking uses of salt. The added sodium and magnesium carbonates tend to preserve its free running qualities. Used daily as the only salt on the table and in cooking it richly supplements the iodine of diets deficient in that element and thus helps to protect against goiter caused by insufficient iodine in the diet.

(1) BRIMFULL BRAND CRYSTAL WHITE SYRUP (2) BRIMFULL BRAND AMBER TABLE SYRUP

Distributor—H A Marr Grocery Company, Denver, Colo., Enid, Okla., Omaha, Neb., and Amarillo, Texas

Manufacturer—Wheeler-Barnes Company, Minneapolis

Description—(1) A table syrup, corn syrup flavored with rock candy syrup. Same as White Oak Brand Crystal Table Syrup, THE JOURNAL, Oct 15, 1932, page 1353

(2) A table syrup, corn syrup flavored with refiners' syrup. Same as Golden Oak Brand Amber Syrup, THE JOURNAL, Dec 3, 1932, page 1948

Claims of Manufacturer—For table use and as a carbohydrate supplement for milk modification in infant feeding

E-JAY BRAND UNSWEETEND EVAPORATED STERILIZED MILK

Distributor—E J Evans Company, Van Wert, Ohio

Packer—Amboy Milk Products Company, Amboy, Ill

Description—Canned, unsweetened evaporated milk the same as Amboy and Melody Brands Unsweetened Evaporated Sterilized Milk (THE JOURNAL, May 7, 1932, p 1655)

TRUPAK APPLE SAUCE

Distributor—Haas Brothers, San Francisco and Fresno, Calif

Packer—Lyndonville Canning Company, Inc., Lyndonville, N Y

Description—Canned apple sauce prepared from peeled and cored apples with added sucrose. Same as VB (Visscher Brothers) Old Fashioned Apple Sauce, THE JOURNAL, Aug 6, 1932, page 476

Claims of Manufacturer—A slightly sweetened apple sauce for table use

SUNKIST PANCAKE FLOUR BLEACHED

Manufacturer—Manev Milling Company, Omaha

Description—Self rising flour containing first clear wheat flour, corn rye and rice flours, dried skim milk, dextrose, calcium acid phosphate, salt and sodium bicarbonate

Manufacturer—The ingredients are thoroughly mixed in a batch mixer and automatically packed in cartons

SATURDAY, MAY 19 1934

LYMPHATICS OF THE SKIN

The part played by lymphatics in various skin phenomena and in skin physiology is generally recognized. Yet knowledge of lymphatics to a large extent has been anatomic, based mostly on the delicate technic of injecting the fine lymphatics in living animals or in dead human tissue. Though a new world of fine anastomosing network of channels was thus revealed, it was only a first step in the knowledge of lymphatic behavior. Observations of living channels is of greater importance and has in fact been extensively achieved on human blood capillaries. Functional knowledge of the capillaries has thus advanced rapidly, especially with the aid of the motion picture camera. The blood capillary is visible and the red corpuscles coursing through bring it into bold relief under appropriate conditions, so that the living channels can be studied directly. The lymphatics, on the other hand are invisible, for their lumens are filled with fluid of the same color and nature as the surrounding tissue juice. Lymphatic channels may be seen, to be sure when they are inflamed as the beaded red streaks of acute lymphangitis, but normally they are hidden. Hence functional knowledge of them has been indirect and based largely on observations on lower animals.

Recently the lymphatics of living human skin have been directly visualized and their behavior has been studied in a striking way. Hudack and McMaster,¹ working at the Rockefeller Institute of New York, have published observations made on themselves and on others by the use of several vital dyes of various diffusibilities following the original use of such colored substances some years ago by Rous.² They have found that intradermal injections with a fine needle tear open the tiny lymphatics, which then readily absorb the solution and are rendered plainly visible. Under the microscope and especially with the motion picture camera a vivid view of these dye-filled channels is revealed and

their behavior under various conditions can be watched. Within a minute or two a minute plexus of extensively anastomosing channels in the superficial layer of the corium is seen. Some of the dye occasionally escapes into the deep lymphatics. While this superficial lymphatic plexus has been described before by anatomists, it was supposed to represent local areas, each acting independently. With the technic mentioned, the wide connections of these anastomosing plexuses were observed for the first time.

The rapidity of lymph flow in these vessels was extraordinary, an observation contrary to the work of previous investigators, who reported that there is almost no lymph flow from a resting limb. With the more nearly ideal conditions used by the New York workers, i. e. normal unanesthetized living human tissue, it was found that dye introduced into the resting forearm reached the axilla within a few minutes. Thus the local injection rapidly became a general one. Since the technic was essentially that used clinically in any intradermal test, it must be assumed that such injections likewise are not local ones, as so often assumed but may reach the general circulation rather quickly. Individual differences in the rapidity of lymph flow also were observed and may prove to be of some significance.

Further physiologic observations concerned the permeability of these tiny channels. It was found that the human lymphatic walls act essentially as a semipermeable membrane, behaving in fact the same as similar vessels in the mouse. The similarity has the practical value of permitting many of the observations in the lower animal to be applied to the solution of human problems in this field. In both species, changes in permeability of the visualized lymphatics are great and rapid. Thus the effect of injury increases this permeability tremendously. Even the slight wheal produced in certain persons by the stroke of a blunt instrument on the skin causes the dye to pass through the lymphatic wall almost as if no barrier existed. Heat, ultraviolet rays and bacterial products have a similar effect. So does histamine. On the other hand, once a wheal is formed it may so compress the lymphatics as to interfere mechanically with the drainage and absorptive function, which becomes so accelerated during moderate inflammation.

Serums and bacterial products are daily being injected into the skin of patients for diagnostic or therapeutic purposes. The great role of the skin in resistance to infection is also realized and emphasized, for the skin presents, so to speak, the first line of defense against the outside world of pathogenic bacteria. Skin diseases in general present many and varied problems. In all these fields the part played by the lymphatics must be an important one. The vital dye technic furnishes a new tool for the investigation of these problems. The fundamental observations here noted point the way to a more complete understanding of skin phenomena in

general and hence may prove applicable to the important field of immunity and resistance. The relative ease of their use would seem to make these dyes of wide value in the clinical investigations of the physiology and pathology of the skin.

NERVOUS STIMULATION TO LACTATION

The unique place occupied by milk in nutrition has been adequately established. Both experimental and practical studies have repeatedly demonstrated that the peculiar chemical constitution of milk admirably fits it for its essential role in the feeding of the young. It is to be expected, therefore, that more than usual attention should be devoted to the biologic circumstances surrounding its elaboration. Lactation is part of the reproductive process both by mechanism and by purposeful association. The mammary gland first enlarges during puberty, and at each successive estrous cycle there is a response in the structure of the gland. From this circumstantial evidence it appears that these changes occur in response to hormone stimulation. This so-called physiologic hypertrophy as well as that produced experimentally in the intact virgin female, spayed female and intact or castrated male by injection of ovarian hormone obtained from the follicle, placenta or pregnant urine consists primarily of an enlargement of the duct system without proliferation of the milk-secreting cells. With parturition, however, there occurs a stimulation to actual secretion from the anterior pituitary; there has been prepared a hormone, prolactin, presumed to be the agent that promotes the activity of the secreting epithelium in the gland whose ducts and supporting tissue have previously been enlarged and thus prepared for the production of milk. Studies on the functional activity of transplants of the mammary gland indicate that the prolactin acts independently of the nerve supply.

Once the milk flow is established, it is well known that its continuance ordinarily depends on the removal of the secretion. The mechanism that correlates the act of milking with the production of additional prolactin and the consequent secretion of more milk has not been clear. In a recent report, Selye¹ describes experiments which indicate that the act of suckling plays an important part in prolonging the active secretion of milk. In studies with rats it was observed that removal of the young from the lactating mother resulted in a disappearance of milk in from three to five days. However if the main duct was cut without injuring the nipples the act of suckling by the young stimulated the secretion of milk to the point of turgidity and rupture of the alveoli. Removal of all the nipples with the consequent absence of suckling led to early cessation of function and atrophy of the glands, yet if some of the nipples were left intact, even though the main duct was cut, all the alveoli secreted actively.

These observations lead to the conclusion that the act of suckling is a nervous stimulus to milk secretion, motivated indirectly through the pituitary. Furthermore, it appears that it is the withdrawal of this stimulus which is responsible for cessation of milk production rather than accumulation of milk in the alveoli.

Evidence indicating that the act of suckling by the young exerts a general nervous response has been cited by Parsons.² In studies on lactating females it was observed that the act of suckling was followed by rises in the urea concentration in the blood, often of considerable magnitude. As the extent of these changes in the blood was not always related to the quantity of milk withdrawn, it was interpreted to mean that suckling produced an emotional response in the mother. It is currently believed that mechanical stimulation plays a part in the secretory activity of many glands, notably certain of those in the gastro-intestinal tract. It has not been determined whether there is usually a hormone involved in the mechanism, though this appears more than likely in view of the foregoing observations on milk production.

SYPHILIS IN PREGNANCY

The increased emphasis on the diagnosis and treatment of syphilis during pregnancy, manifest in current medical literature,¹ may be considered an indication of past neglect of this significant topic. Accurate statistics on the incidence of syphilis in private obstetric practice are lacking. Even allowing for a much lower rate than is shown elsewhere, however, it is apparent that meticulous attention should be given to syphilis in all pregnancies without exception.² Among the clinic class of patients the frequency of syphilis in pregnancy varies, largely dependent, apparently, on geographic and racial factors. Thus, in a recent summary³ of the incidence reported by various authors, there was a variation from 12 per cent from the University of Oklahoma to 34 per cent among colored in Atlanta. In general, however, from 5 to 10 per cent of pregnant women (white clinic class) are syphilitic. The percentage is noticeably higher among the Negroes. Corroboratory evidence is presented by Cole and his collaborators⁴ in studies based on 3,817 syphilitic women in five cooperating clinics. Of the 603 of this group who experienced pregnancy during or after treatment for their infection, 277 were white and 326

were colored. It was noted that there was a higher percentage of latent cases of syphilis among the colored than among the white, thus suggesting either neglect on the part of the colored in seeking early and adequate treatment or a high incidence of symptomless infection in Negroes.

The difficulties in the way of diagnosis of syphilis in pregnant women are more apparent than real. From the history and physical examination alone the diagnosis can be made in from 25 to 64 per cent of the cases.³ Routine use of serologic methods, preferably before, during and after pregnancy, materially increases the proportion of correct diagnoses. Even in the presence of the disease the serologic reaction is of important prognostic significance. Thus a negative Wassermann reaction in syphilitic mothers during pregnancy insures a higher percentage of living and apparently nonsyphilitic children than does a negative Wassermann reaction before the pregnancy.⁴

The relation of time of diagnosis and initiation and character of treatment on the ratio of miscarriages, stillbirths and syphilitic children has been the subject of numerous investigations. In a group of 268 pregnancies reported by McKelvey and Turner⁵ in which the mother had not received treatment either before or during pregnancy, 45.9 per cent resulted in a still-born infant and 54.1 per cent were born alive. Among the living infants in whom the ultimate status was known, 35.4 per cent were normal and 64.5 per cent were demonstrated clinically or at necropsy to have syphilis. Rising from this group with poor prognosis from the standpoint of the child, statistics are available showing an improving outlook depending on the stage of pregnancy in which treatment is instituted. Thus, 78 per cent of pregnant syphilitic mothers in whom treatment was instituted before the fifth month bore living, apparently nonsyphilitic, children as contrasted with only 61 per cent when treatment was started later. There were, moreover, more than three times as many syphilitic children in the latter group as in the former.⁴ The adequacy of antisyphilitic treatment has an additional significance. When ten injections of an arsenical and ten of a heavy metal were given before the fifth month of the pregnancy, living, apparently nonsyphilitic, children resulted in 91 per cent of the cases. When much of the arsenical and little of the heavy metal was used, the percentage of nonsyphilitic children fell to 85, and when little arsenical and much heavy metal was employed, to 75.⁴ The best results are therefore obtained when adequate treatment consisting of both an arsenical and a heavy metal is instituted early. Still better results occur when antisyphilitic treatment is given both before and during pregnancy.

These observations are applicable in private practice as well as in the clinic. The woman of child-bearing

age should be given the best possible chances of having a living, healthy child. Careful history and physical examination of every pregnant woman, with syphilis in mind, should certainly not be omitted. Routine serologic tests preferably before, and certainly as early as possible in, pregnancy should invariably be performed.

Current Comment

THE LIPIDS OF EPITHELIAL TISSUE

Epithelial tissue not only is a protective covering but also appears to have a metabolism of its own. The lipid fraction of this tissue seems to be intimately associated with definite important aspects of this metabolism, recent investigations indicate that the secretion of lipids is characteristic of all epithelial tissue and contains a relatively high proportion of sterols. The experiments of Sperry and Angevine¹ have demonstrated this fact for intestinal mucosa, Schonheimer and Hrdina² have found large amounts of sterols in the secretion of the colon. Further evidence for a production of unsaponifiable lipids by the intestinal epithelium is reported by Burger and Oeter.³ These investigators analyzed the mucosa of the large bowel and concluded that the sterol content was not sufficient to support the view that the high concentration of these substances in the feces is due to desquamated mucosa, a secretion of sterols by the intestine was therefore postulated. The important functions that have been assigned to these lipids of the epithelial tissue emphasize the value of more specific information concerning their chemical nature. Of particular interest are the fatty substances of the skin, the fact that the latter contain a precursor of vitamin D is sufficient to warrant their detailed study. In addition, the germicidal or immunologic properties of the skin and the maintenance of the normal physical state of this tissue have been related to its content of fat. An investigation of the chemical composition of the lipids of the skin has been reported from the Washington University School of Medicine in St. Louis.⁴ Analyses were made of both the fatty material of the surface of the skin and that from the stratum corneum, the most striking finding was the high concentration of unsaponifiable material. Of the latter group of substances, the sterols represented two thirds of the total in the case of the stratum corneum lipids and slightly less than half of the unsaponifiable fraction of the superficial skin lipids. The saponifiable fractions were characterized by a high content of free fatty acids, in contrast to the relatively small amount of uncombined fatty acids found in most body tissues. These results are additional evidence of the excretion of lipids by epithelial tissues, they suggest important metabolic functions and chemical importance for these substances and show the need for further fundamental knowledge concerning the chemistry of epithelial tissue.

EMBRYONIC TISSUE "ORGANIZERS"

The rapidly increasing knowledge of the intrinsic growth factors in embryonic tissue cells has suggested numerous working hypotheses in many fields of clinical research. For example, its application has led to the apparently successful production of quasimalignant conditions in frogs. Embryologists have found that growth and differentiation of early embryonic tissues are determined largely by intracellular "organizers" or chemical "inductors." These local growth hormones are thermostable, resembling in this particular certain organ-specific lipoids.¹ In some embryonic tissues these inherent growth factors are held in check by relatively unstable chemical "inhibitors,"² which resemble serum complement in that they can be inactivated by heat or by other deleterious factors. Such inactivation releases the previously latent local growth stimulants. Making use of this lability, Witschi³ of the University of Iowa zoological laboratory allowed frog's eggs to undergo spontaneous degeneration for from three to five days before fertilization. Certain of the growth inhibitors were apparently lost or inactivated by this process. From these senile or overripe eggs, atypical frog embryos developed. These were characterized by low grade cellular differentiation and by a tendency to tumor formation, melanotic cell masses, for example, being found in internal organs. Since such senile embryos rarely live more than two weeks, Witschi resorted to the expedient of transplantation into normal tadpoles. These tadpoles afterward developed into mature frogs. Most of the transplants underwent degeneration. A few, however, remained alive. Aggressive, invasive tumor growth took place in the peritoneal cavities, with secondary nodules occasionally appearing in distant organs or tissues. The transferable cell masses, therefore, had properties simulating malignancy.

Association News

THE CLEVELAND SESSION

Alumni Dinner of Washington University School of Medicine

The alumni dinner of the Washington University School of Medicine will be held on Tuesday evening, June 12, at 6 30, at the Hotel Statler.

Alpha Omega Alpha Lecture at Annual Session

The annual Alpha Omega Alpha dinner and lecture will be held in Cleveland at the Hotel Statler on Thursday evening, June 14. The speaker, Dr. Lewellys F. Barker (Baltimore), will discuss the life of Dr. William H. Welch.

Dinner of Section on Orthopedic Surgery

The annual get-together dinner of the Section on Orthopedic Surgery will be held at the Westlake Hotel, Rocky River, Ohio, Wednesday evening, June 13, at 7 30. This will be preceded by a lake ride, yachts leaving East Ninth Street Pier, which is about two blocks east and one-fourth mile north of the Auditorium Building, for Rocky River at 6 o'clock. In case of inclement weather, Westlake taxicabs will leave the

Tickets will be for sale at \$2 at the meeting hall in the Auditorium.

MEDICAL BROADCASTS

National Broadcasting Company

The American Medical Association broadcasts on a coast-to-coast network each Monday afternoon from 4 to 4 15 Central daylight saving time (4 o'clock Eastern standard time, 3 o'clock Central standard time, 2 o'clock Mountain standard time, 1 o'clock Pacific standard time).

The next three broadcasts will be as follows:

May 21 Disease by Air, W. W. Bauer, M.D.
May 28 The Family Medicine Chest, Morris Fishbein, M.D.
June 4 The Hazards of Summer, Morris Fishbein, M.D.

Columbia Broadcasting System

The Association broadcasts on a Western network of the Columbia Broadcasting System each Thursday afternoon on the Educational Forum from 4 30 to 4 45, Central daylight saving time. The next three broadcasts will be as follows:

May 24 Character of a Quack, Morris Fishbein, M.D.
May 31 Health Slogans, W. W. Bauer, M.D.
June 7 The First Month, W. W. Bauer, M.D.

Medical News

(PHYSICIANS WILL CONFER A FAVOR BY SENDING FOR THIS DEPARTMENT ITEMS OF NEWS OF MORE OR LESS GENERAL INTEREST SUCH AS RELATE TO SOCIETY ACTIVITIES, NEW HOSPITALS, EDUCATION, PUBLIC HEALTH, ETC.)

CALIFORNIA

Rural Health Service—Dr. Ira O. Church, health officer of Alameda County, has appointed Dr. Luther Michael, district health officer to serve San Leandro and a large part of the unincorporated territory surrounding that city; Dr. Paul E. Dolan, health officer of Livermore, the rural district of Murray Township, within which Livermore is located; Dr. Richard Heinz, health officer of Pleasanton, Pleasanton Township; Dr. Elmo M. Grimmer, Irvington, Washington Township; and Dr. John A. Azevedo, that portion of Eden Township which surrounds Hayward, while Nelson C. Clemens, D.V.M., continues as health officer of that city. All district officers are serving the county health department without financial reimbursement.

COLORADO

Society News—A tissue study conference, devoted to "Pathology of the Thyroid Gland," was held by the Colorado Society of Clinical Pathologists, April 21, led by Drs. William C. Black and George Z. Williams, Denver. Dr. Richard W. Whitehead gave an illustrated lecture in the evening on "Newer Advances in Endocrinology." The next meeting of the society will be held in October—Dr. George B. M. Baker, Rocky Ford, addressed the Crowley County Medical Society at Ordway, April 11, on "Orchitis: Its Cause and Treatment." At a meeting of the El Paso County Medical Society, April 11, speakers included Drs. Alfred L. Briskman, Colorado Springs, on "Arterial Hypertension: Its Prognostic Significance"; Bernhard B. Gloeckler, Colorado Springs, "Multiple Sclerosis"; Frank T. Stevens, Colorado Springs, "Differential Diagnosis in Multiple Sclerosis"; and Von H. Brobeck, Colorado Springs, "The Eyes in Multiple Sclerosis."—Dr. Roy E. Davis, Pueblo, discussed onchocerciasis before the Pueblo County Medical Society, April 17.

DISTRICT OF COLUMBIA

Medical Bills in Congress—H. R. 6130 has been reported to the House with recommendation that it pass, proposing to prevent misrepresentation and deception in the sale of milk and cream in the District of Columbia.

Society News—The Washington Urological Society was addressed April 30 by Drs. John H. Morrissey and Moses Swick, New York, on "Phases of Prostatic Resection" and

"Excretion Urography," respectively—Speakers before the Washington Medical and Surgical Society, March 26, included Dr Joseph F Elward on "X-Ray Diagnosis of Gastric Carcinoma" Dr John C Eckhardt, among others, addressed the society, recently, on "Calcium in Asthma"

ILLINOIS

Dr Williams Honored—The Adams County Medical Society held a banquet in honor of Dr William W Williams, Quincy, March 12, in recognition of his completion of fifty years in the practice of medicine Dr Nathaniel G Alcock, Iowa City, presented a floral tribute on behalf of the University of Iowa College of Medicine, where Dr Williams graduated in 1884, and Dr Philip H Kreuscher, Chicago, president, Illinois State Medical Society, presented a gold watch on behalf of the Adams County Medical Society Dr Williams has practiced in Quincy for thirty-nine years On the scientific program, Dr Alcock discussed resection of the prostate, and Dr Kreuscher, backache

Society News—Dr David C Todd, St Louis, recently addressed the Macoupin County Medical Society in Carlinville on the economic side of the general practice of medicine—At a meeting of the Franklin County Medical Society in Benton, April 26, speakers included Dr Max S Wien, Chicago, on "Relation of Dermatology to General Medicine"—Drs George T Palmer, Springfield, and George H Vernon Jr discussed "Blood Sedimentation in General Practice" before the Christian County Medical Society in Taylorville, April 18—At a meeting of the Jefferson-Hamilton County Medical Society in Vernon, April 12, Dr James A Warner, St Louis, spoke on treatment of bacterial diseases—A symposium on cancer was presented before the La Salle County Medical Society in La Salle April 25, by members of the staff of Washington University School of Medicine, St Louis Drs Isaac Y Olch, James Barrett Brown and Nathan A Womack

Chicago

United Medical Service, Inc, Sued—Quo warranto proceedings were instituted, May 12, in the Superior Court, Cook County, by the attorney general of Illinois, questioning the right of the United Medical Service, Inc, 23 East Jackson Boulevard, to engage in the corporate practice of medicine under the provisions of the medical practice act of Illinois The United Medical Service, Inc, was organized as an Illinois corporation and chartered, Dec 15, 1930, with an authorized capital stock of \$40,000 (THE JOURNAL, Oct 8, 1932, p 1267) Dr Joseph G Berkowitz, formerly director of the Public Health Institute, is president of United Medical Service, Inc

Society News—Dr George H Weaver was elected president of the Society of Medical History of Chicago, May 2, Dr David J Davis, vice president, and Dr Irving S Cutter, secretary—Speakers before the Chicago Orthopedic Club, May 11, were Drs Marcus H Hobart on "Myositis Ossificans," Ferdinand C Seidler, "Fracture Dislocation of the Shoulder," and Henry Bascom Thomas, "Undifferentiated Osteogenic Sarcoma"—The Chicago Gynecological Society was addressed, May 18, by Drs James E Fitzgerald on "Management of Pregnancy in Women with Heart Disease," and Lester E Frankenthal Jr, "The Cardiac Patient in Pregnancy, with a Report of a Case of Coronary Occlusion During Pregnancy" Among others, Drs Leonard E Markin and Leon Bloch will speak before the Chicago Society of Allergy, May 21, on "Allergic Colitis"—Speakers before the Chicago Ophthalmological Society, May 21, will review a century of progress in ophthalmic therapeutics, ophthalmic teaching and ophthalmic surgery, they will be Drs Oscar Dodd, Evanston, Ill William E Gamble Los Angeles and Harry Woodruff, Joliet, Ill—Dr Percival Bailey will discuss "Peculiarities of Tumors of the Nervous System in Infants and in Childhood" before the Chicago Pediatric Society, May 22

INDIANA

Tuberculosis Meeting—Dr Merlin H Draper, Fort Wayne, was elected president of the Indiana Tuberculosis Association at the twenty-third annual meeting in Indianapolis, April 17-18 Speakers at the scientific sessions included

- Dr Harry E Kleinschmidt New York Can Modern Medicine Abolish Tuberculosis?
- Dr Harvey L Murdock Fort Wayne When Should Hygiene Treatment of Tuberculosis Be Concluded?
- Dr Paul D Cimm Evansville Illustrated Demonstration of Thoracic Surgery
- Dr Willis D Gatch Indianapolis Surgery in the Treatment of Tuberculosis

Society News—Dr Robert B Osgood, Boston, addressed the Fifth District Medical Society in Terre Haute, May 4, on "Treatment of Arthritis"—Dr Edward A Oliver, Chicago, will address the Tenth District Medical Society, May 29, on "Diagnosis and Treatment of Some of the Commoner Skin Diseases"—Dr William F Hughes, Indianapolis, discussed common diseases of the eye before the Cass County Medical Society in Logansport, April 20—At a meeting of the Posey County Medical Society in New Harmony, April 12, Dr Thomas F Reitz, Evansville, spoke on coronary occlusion—The Porter County Medical Society was addressed in Valparaiso, April 24, by Dr Herbert E Landes, Chicago, on genito-urinary diseases

IOWA

Society News—A recent meeting of the Boone Story County Medical Society in Nevada was addressed by Drs Homer S Elmquist, Cambridge, and George J Severson, Slater, on "Diseases of the Blood" and "Purpura Hemorrhagica," respectively—Speakers before the Calhoun County Medical Society in Rockwell City recently were Drs Oscar R Prettyman, Manson, and Louis E Eslick, Rockwell City, on urinalysis and general practice, respectively—Dr Clifford J Barborka, Chicago, addressed the Clinton County Medical Society in Clinton, recently, on "Present Conception of the Relation of Diet to Health and Disease"—Dr Frederick L Nelson, Ottumwa, addressed the Davis County Medical Society in Bloomfield in March on "Diagnosis of Surgical Urology"—The March meeting of the Sac County Medical Society was addressed, among others, by Dr Fred L Knowles Fort Dodge, on "Care of Fractures of the Neck of the Femur"—At a meeting of the Scott County Medical Society in Davenport, recently, Dr Carl A Hedblom, Chicago, spoke on "Treatment of Pulmonary Abscess and Empyema"—Dr Charles Mayo, Rochester, Minn, will discuss "Glandular Regulators of Physiologic Activity" before the Linn County Medical Society, Cedar Rapids, June 7

KANSAS

Society News—Dr Don Carlos Peete, Kansas City, discussed "Myocarditis, with Special Reference to Myocardial Damage Resulting from Influenza" before the Douglas County Medical Society, recently—At a meeting of the Shawnee County Medical Society, recently, Dr Merritt Paul Starr, Chicago, spoke on "Treatment of Pernicious Anemia" April 2, Dr John A Crabb, Topeka, spoke on "Synergistic Bacterial Gangrene of the Abdominal Wall," and Mr Ross L Laybourn, bacteriologist "Problems in the Transmission of Bacterial Disease"—Speakers before the Wyandotte County Medical Society, Kansas City, May 1, included Dr Lee V Hill on "Diagnosis and Treatment of Infections of the Hand, with Anatomical Demonstrations"

KENTUCKY

Survey of Syphilis—The bureau of venereal diseases of the state board of health has announced a survey of prenatal and congenital syphilis in counties throughout the state, to be made by a field nurse in cooperation with county health departments, practicing physicians and civic groups Efforts will be made to have all cases brought under treatment, either by family physicians or by health officers, the latter confining themselves to the indigent

University News—About fifty rare medical books, principally on diseases of the lungs and of the skin, were recently given to the University of Kentucky by a senior student, Ralph G Edwards The books were formerly the property of physicians in his family and their publication dates range from 1820 to 1840 Another gift consisted of 175 volumes of medical works, note and account books of the late Dr John W Crenshaw Versailles, presented by his daughter A third gift of 100 volumes was given by Dr John C Lewis, Lexington, son of the late Dr John A Lewis, Georgetown It includes several volumes of early transactions of the Kentucky State Medical Society and copies of the *Richmond and Louisville Medical Journal* from 1871 to 1876

LOUISIANA

State Medical Election—Dr Courtland P Gray Sr, Monroe, was chosen president-elect of the Louisiana State Medical Association at its annual meeting in Shreveport in April and Dr Stanford Chaille Jamison, New Orleans, was inducted into the presidency Vice presidents elected are Drs Marcy J Lyons, New Orleans Joseph M Gorton, Shreveport and Rhett G McMahon Baton Rouge and Paul T Talbot, New Orleans, was reelected secretary

MASSACHUSETTS

Health Education Session—The New England Health Education Association will convene for its annual conference, June 1-2, at the Massachusetts Institute of Technology, Boston. Among others, Dr. Wilson G. Smullic, professor of public health administration, Harvard University School of Hygiene and Public Health, will discuss present stage of research into the cause of the common cold, and Prof. Edward C. Lindeman of the New York School of Social Science, adult health education.

Society News—Dr. Clarence B. Gay, Fitchburg, was elected president of the Worcester North District Medical Society at its seventy-fifth annual meeting, April 25, in Fitchburg. Dr. Andrew R. MacAusland, Boston, delivered the annual oration on "Recent Trends in the Treatment of Fractures."—Dr. Richard M. Smith addressed the South End Medical Club in Boston, April 17, on "Acute Abdominal Conditions in Children."—Dr. Frederick T. Lord, Boston, was chosen president of the Massachusetts Tuberculosis League at its annual meeting, April 12. Speakers included Drs. Henry D. Chadwick, state health commissioner, and Kendall Emerson, New York.—Dr. Leybourne Stanley P. Davidson, professor of medicine, University of Aberdeen, addressed the Harvard Medical Society, April 10, on "Incidence, Etiology and Treatment of Nutritional Anemia."

MICHIGAN

Alumni Day Clinics—The annual Alumni Day of Detroit College of Medicine and Surgery, now the Wayne University College of Medicine, will be held June 7. Diagnostic medical clinics will be conducted by Dr. Charles P. Emerson, professor of medicine, Indiana University School of Medicine, and Dr. William C. MacCarty, director of the department of surgical pathology of the Mayo Clinic. In addition they will hold a clinicopathologic conference, and a skin clinic has been arranged by the Detroit Dermatological Society. Dr. James W. Inches will be the principal speaker at the evening banquet which will be a testimonial to Drs. Angus McLean, Don M. Campbell and Andrew P. Biddle. Detroit College of Medicine and Surgery was merged in January with other city colleges to form Wayne University and at that time assumed its present title.

MINNESOTA

Radiologic Meeting—Included among the speakers at the winter meeting of the Minnesota Radiological Society at the University Hospital, Minneapolis, March 10, were the following:

- Dr. Leo G. Rigler, Minneapolis: Roentgenologic Studies of Multiple Births.
- Dr. John B. Eneboe, Incidence of Para Esophageal Hernia in Pregnant Women.
- Dr. Joseph T. King and Karl W. Stenstrom, Ph.D.: Radiation Effects on Tissue Cultures of Lymph Nodes.
- Dr. Jacob Sagel: Benign Strictures of the Stomach.
- Dr. Kano Ikeda: Roentgen Observations on Acute Amebic Colitis.
- Dr. Byrl R. Kirlin, Rochester, The American Board of Radiology.
- Dr. William T. Peyton: Observations on Diagnosis and Treatment of Malignancy.

Lectureship in Honor of Dr. Carman—An annual lectureship in radiology has been established in honor of the late Dr. Russell D. Carman, the Minnesota Radiological Society announces. It is to be known as the Russell D. Carman Memorial Lecture, and the first in the series will be given by Dr. Alexander B. Moore, Washington, D. C., at the meeting of the Minnesota State Medical Association in Duluth, July 16. At this meeting Dr. Donald C. Balfour, Rochester, will also deliver an address on the life of Dr. Carman, whose entire career was devoted to roentgenology. He held several teaching positions in his specialty and from 1913 until his death was head of the section on roentgenology at the Mayo Clinic. He was also professor of roentgenology in the Graduate School of the University of Minnesota. He served as president of the American Roentgen Ray Society and of the Radiological Society of North America.

MISSOURI

University News—The class of 1899 of Missouri Medical College will hold a reunion at the University Club, June 9 in St. Louis. Dinner will be at six o'clock. Plans have been changed since the announcement in THE JOURNAL, May 12, p. 1578. Further information may be had from Dr. J. Clay Heinrichs, 306 North Grand Avenue, St. Louis.

Dinner for Colonel Skinner—Col. George A. Skinner, surgeon of the seventh corps area, U. S. Army, was honored

at a dinner at Hotel Melbourne, St. Louis, April 19. Colonel Skinner has been conducting an inactive duty training period for officers of the medical department of the reserve corps at St. Louis University. Speakers included Lieut. Col. Theodore P. Brooks, Col. William E. Leighton, Major Amand N. Ravold, Lieut. Col. Norville W. Sharpe, Major James E. Phillips, Major John R. Hall, Major Lee D. Cady and Major Millard F. Arbuckle. A certificate of esteem was presented to Colonel Skinner, who will soon retire from active service.

Society News—Dr. Willis C. Campbell, Memphis, addressed the Pettis County Medical Society at Sedalia, April 16, on "Ankylosis of Joints."—Speakers before the Linn County Medical Society recently included Drs. Charles C. Conover and Theodore H. Aschmann, Kansas City, on "Circulation of the Myocardium in Health and Disease" and "Causes and Treatment of Sterility," respectively.—At a meeting of the Caldwell-Livingston County Medical Society in Clullicoth, March 12, Drs. John H. Ogilvie and George E. Knappenberger, Kansas City, discussed hyperthyroidism and hyperemotionalism in the nervous state, respectively.—Dr. Noe F. Chostner discussed the "Diagnosis and Preoperative Treatment of Acute Appendicitis" before the Cape Girardeau County Medical Society at Cape Girardeau, March 12.

NEBRASKA

State Medical Meeting at Lincoln—The annual meeting of the Nebraska State Medical Association will be held at the Cornhusker Hotel, Lincoln, May 22-24, under the presidency of Dr. Joseph Bixby, Geneva. Guest speakers listed on the tentative program are:

- Dr. Walter L. Biering, Des Moines, Iowa, subject not announced.
- Dr. Walter A. Fansler, Minneapolis: Malignancies of the Colon.
- Dr. Edwin P. Sloan, Bloomington, Ill.
- Dr. Thomas G. Orr, Kansas City, Mo.: Acute Peritonitis.
- Dr. Clifford J. Barborka, Chicago: Diets and Disease.
- Dr. Kellogg Speed, Chicago: Knee Joint Injuries.

Among Nebraska physicians on the program will be:

- Dr. John V. Reilly, Grand Island: Pseudoparalysis in Childhood.
- Dr. Robert Bruce Eldredge, Omaha: Intravenous Therapy in Pediatrics.
- Dr. Harry H. Everett, Lincoln: Choice of Operation in Disease of the Biliary Tract.
- Dr. Maurice C. Howard, Omaha: Management of Hemorrhage in Peptic Ulcer.
- Dr. James Dewey Bisgard, Omaha: Treatment of Chronic Empyema.
- Dr. Benjamin F. Loran, Auburn: Federal Funds for Physicians Rendering Service to the Indigent.
- Dr. Samuel A. Swenson, Oakland: Cancer with Special Reference to Palliative Treatment.
- Dr. William A. Colburn, Lincoln: Treatment of Infantile Eczema.

NEW JERSEY

Society News—Dr. William P. Healy, New York, addressed the Atlantic County Medical Society, Atlantic City, May 11, on cancer of the female pelvic organs.—Dr. Frederick William Sunderman, Philadelphia, discussed diabetes before the Gloucester County Medical Society, Pitman, April 19.—Drs. Percy S. Pelouze, Philadelphia, and Arthur J. Casselman, Camden, addressed the Bergen County Medical Society, Hackensack, May 8, on "Gonorrhea in the Male and Its Treatment" and "Cooperation in the Control of Gonorrhea and Syphilis," respectively.—The program of the Hudson County Medical Society was presented by the staff of Greenville Hospital, Jersey City, May 1, as follows: Drs. Robert H. Stockfisch, "Neurologic Procedure for the General Practitioner," and Solomon Ben Asher, "Use of Quinidin in Heart Affections." Dr. Leo J. Ward, Elizabeth, demonstrated unusual and interesting roentgenograms.

NEW YORK

Society News—Dr. Richard B. Cattell, Boston, addressed the Ontario County Medical Society, Clifton Springs, April 10, on diagnosis and treatment of carcinoma of the colon.—Dr. Oswald S. Lowsley, New York, was the speaker at the annual dinner of the Geneva Academy of Medicine, April 19, on "Diagnosis and Surgical Treatment of Kidney Pathology."—Dr. Roscoe R. Graham, Toronto, Ont., addressed the Rochester Academy of Medicine, April 5, on surgical therapy in duodenal ulceration.—Drs. Andrew Macfarlane and Thomas Parran, Jr., addressed the Medical Society of the County of Albany, April 25, on "The Family Physician Past, Present and Future" and "Health Services of Tomorrow," respectively.—Speakers at the spring meeting of the Chautauque County Medical Society, Fredonia, in March were Drs. James H. Borrell and John M. Barnes, Buffalo, on "Common Urological Conditions" and Roy G. Pfotzer, Buffalo, "What to Expect from an Electrocardiogram."—Dr. Edgar W. Phillips, Rochester, addressed the Niagara County Medical Society, March 13, on surgery in pulmonary tuberculosis.

New York City

Biggs Memorial Lecture—The Hermann M. Biggs Memorial Lecture of the New York Academy of Medicine was given by Dr Arthur J. Bedell, Albany, on "Causes and Prevention of Blindness," May 3.

Sydenham Hospital Adopts Group Plan—A plan of group hospitalization to be placed in operation by fall has been announced by Sydenham Hospital. Single persons earning not more than \$3,000 and married persons earning not more than \$5,000 will be entitled to three weeks' hospitalization for \$10 a year. Laboratory work and treatments will be furnished at cost, the maximum fee for any patient not to be more than \$100 even in cases of operation. No charge will be made for use of operating room and anesthesia.

Annual Art Exhibit—The New York Physicians' Art Club held its seventh annual art exhibit at the New York Academy of Medicine early in April. About 300 pictures were entered, but the exhibition also included sculpture, wood carving, jewelry, lithographs and etchings. About seventy physicians contributed, including Drs Otto P. Diederich, Fresno, Calif., Isaac Seth Hirsch, Walter Beran Wolfe, Paul E. Bechet, Solomon Stan Bauch, Alpheus Freeman, Arnold Galambos, Winfred M. Hartshorn, Alfred Braun, Louis Rachlin and Henry S. Patterson.

Conference on Artificial Fever—The fourth annual conference on fever was held at the College of Physicians and Surgeons of Columbia University, April 27, under the chairmanship of Dr. William Bierman. Among the speakers were

Dr. Walter M. Simpson, Dayton, Ohio, Report of Progress in Artificial Fever Studies at Miami Valley Hospital
Drs. Ferd D. Streeter and Stafford L. Warren, Rochester, Further Observations on Cases of Dementia Paralytica Treated with Artificially Induced Fever
Drs. Bierman and Edward A. Horowitz, Results of Hyperpyrexia in Gynecologic Conditions
Dr. Charles L. Short, Boston, General Diathermy in Treatment of Rheumatoid Arthritis
Dr. Heinrich F. Wolf, Willard Parker Hospital, Application of Hyperpyrexia to Monkeys Infected with the Virus of Poliomyelitis

Officers of Society for Prevention of Asphyxial Death—The board of directors of the Society for the Prevention of Asphyxial Death elected the following officers at a meeting, March 29: Dr. Paluel J. Flagg, president, Col. Charles R. Reynolds and Dr. Pol N. Coryllos, vice presidents, and Capt. Ernest W. Brown, M. C., U. S. Navy, Washington, D. C., secretary. The board of directors has recently been reorganized with the following members:

Captain Brown	Dr. Richard N. Pierson, New York
Dr. Ethan F. Butler, Elmira, N. Y.	Colonel Reynolds
Dr. Coryllos	Dr. Royd R. Sayers, U. S. Public Health Service, Washington, D. C.
Dr. Henry Hall Forhes, New York	Dr. Amos O. Squire, Ossining, N. Y.
Dr. Lee M. Hurd, New York	Dr. Cassius H. Watson, New York
Dr. Chevalier L. Jackson, Philadelphia	Dr. Joseph S. Wheelwright, New York
Dr. John Devereux Kernan, New York	Dr. Horatio B. Williams, New York
Dr. Harrison S. Martland, Newark	
Dr. Matthias Nicoll, Jr., White Plains, N. Y.	
Dr. Charles Norris, New York	
Dr. George Ornstein, New York	

NORTH DAKOTA

Personal—Dr. George M. Williamson, Grand Forks, secretary, state board of medical examiners, was guest of honor at a dinner given by the Minneapolis editorial board of the *Journal-Lancet*, February 15. Dr. and Mrs. Andrew Carr, Minot, celebrated their golden wedding anniversary recently. Dr. Carr is a past president of the North Dakota State Medical Association.

Society News—The North Dakota Hospital Association was recently organized at Bismarck with Mr. J. T. Tollefson, Fargo, president, and Dr. Henry L. Halverson, Minot, secretary. Sixteen hospitals were made charter members. Dr. Ruth M. Mahon, Grand Forks, addressed the Grand Forks District Medical Society, March 21, at Grand Forks, on blood dyscrasias. Drs. William T. Peyton, Minneapolis, and Leonard W. Larson, Bismarck, discussed tumors of the breast at a meeting of the Sixth District Medical Society, Bismarck, in March.

OHIO

Dr. Bachmeyer Resigns as Dean—Dr. Arthur C. Bachmeyer, dean of the University of Cincinnati College of Medicine for the past nine years, recently submitted his resignation, effective September 15. Dr. Bachmeyer will continue as superintendent of the Cincinnati General Hospital and as professor of hospital administration.

Society News—A symposium on pediatrics was presented before the Summit County Medical Society, Akron, May 1, by Drs. Ray S. Friedley, James G. Kramer, Joseph M. Ulrich, William D. Lyon and Myrl M. Miller. Dr. Walter C. Alvarez, Rochester, Minn., addressed the Academy of Medicine of Cleveland, May 18, on "Some Causes of Nervous Indigestion." Dr. Harry H. McClellan, Dayton, addressed the Washington County Medical Society, April 11, on "Physical Causes of Mental and Nervous Diseases." A symposium on chronic abdominal pathology was presented before the Miami County Medical Society, Troy, April 6, by Drs. James R. Caywood and Robert D. Spencer, Piqua, and Don F. Deeter, Pleasant Hill. Drs. Myron Eli Millhon and Howard E. Boucher, Columbus, addressed the Pickaway County Medical Society, Circleville, April 6, on medical and surgical treatment, respectively, of diabetes. Dr. Donald E. Yochem, Newark, addressed the Licking County Medical Society, Newark, March 30, on recent developments in diseases of the chest. Dr. Ralph F. Massie, Ironton, discussed treatment of varicose veins at a meeting of the Hempstead Academy of Medicine, Portsmouth, April 9. Dr. Max Cutler, Chicago, will address the Cincinnati Academy of Medicine, May 21, on "Indications and Limitations of Radium in the Treatment of Cancer."

OKLAHOMA

Society News—Dr. Cyrus C. Sturgis, Ann Arbor, Mich., addressed the Ottawa County Medical Society in March on the anemias. Drs. Marvin E. Stout, Oklahoma City, and Raymond G. Jacobs, Enid, addressed the Garfield County Medical Society, Enid, March 29, on "The Ruptured Appendix" and "Pelvic Inflammatory Disease Treated by the Elliott Method," respectively. Drs. Paul C. Carson, and Ernest M. Seydell, Wichita, Kan., addressed the Kay County Medical Society, Ponca City, March 22, on heart disease in children and removal of foreign bodies by the bronchoscope, respectively. Physicians who addressed the Carter County Medical Society, Ardmore, March 5, were Drs. Arthur W. White, Oklahoma City, on peptic ulcer, LeRoy D. Long, Oklahoma City, gonor, and Leonard S. Willour, McAlester, cooperative medicine, basic science and public health. Drs. Hugh G. Jeter and Grider Penick, Oklahoma City, discussed anemia and pelvic tumors, respectively, before the Cleveland County Medical Society at a meeting at the state hospital, Norman, March 8.

PENNSYLVANIA

Society News—The medical and dental societies of Delaware County were guests of the Delaware County Pharmacists' Association in Chester, May 10, mutual medical problems were discussed by Drs. Wilmer Krusen, Philadelphia, and Ralph E. Bell, Media. Harry Cornfeld, Ph.D., Collingdale, and S. B. Luckie, D.D.S., Chester. Dr. Meredith F. Campbell, New York, addressed the Pittsburgh Urological Association, May 14, on "Lower Urinary Tract Obstruction in Infants and Children."

Philadelphia

Portrait Presented—A portrait of the late Dr. David Bushrod James, once professor of gynecology at Hahnemann Medical College and Hospital, was presented to the college by the professional staff at a memorial meeting, April 20. Dr. Earl B. Craig, successor to Dr. James, made the presentation.

Personal—Dr. John A. Kolmer, professor of medicine, Temple University School of Medicine, was elected director and president of the board of trustees of the Research Institute of Cutaneous Medicine, April 26. The institute was founded in 1922 by Drs. Kolmer, George Raiziss and the late Jay Frank Schamberg. Dr. Henry B. Ingle was recently elected president of the Philadelphia alumni society of the University of Pennsylvania School of Medicine.

Premedical Requirements Raised—The faculty of the Woman's Medical College of Philadelphia recently recommended after a study of records of its students that applicants for admission in September 1935 be required to present evidence of completion of three years of premedical college study. The corporation of the college confirmed the recommendation. Special consideration will be given to cases in which unusual ability or equivalent training may warrant exceptional action.

Society News—"Jefferson Medical College Night" was observed at the meeting of the Philadelphia County Medical Society, April 25, with the following speakers: Drs. Baxter L. Crawford and Thomas C. Stellwagen, Jr. on tumors of the kidney, and Martin E. Rehfuess and Edward J. Klopp, diseases of the gallbladder. Drs. Francis C. Grant and Stuart V.

Rowe, among others, addressed the Philadelphia Neurological Society, April 27, on "Neurogenic Origin of Duodenal Ulcer" and "Localization of the Sleep Mechanism," respectively

VIRGINIA

Society News—The Norfolk County Medical Society held its annual all day clinic, April 11, at the Hospital of St Vincent de Paul and Protestant Hospital, Norfolk. In the evening Dr J Shelton Horsley, Richmond, delivered an address on "Symptoms, Diagnosis and Treatment of Carcinoma of the Gastro Intestinal Tract"—Dr Charles Howard Marcy, Pittsburgh, was a guest speaker at the annual meeting of the Virginia Tuberculosis Association at Richmond, April 5, on "Tuberculosis in the Negro"—The Virginia Society of Otolaryngology and Ophthalmology held its annual meeting in Lynchburg, May 5, with Drs Samuel J Crowe, Baltimore, and John H Dunnington, New York as guest speakers—Edward L Corey, Ph D, and Edwin P Johnson, DVM, addressed the University of Virginia Medical Society, March 5, on "Physiology of the Mammalian Fetus and 'Etiology and Histogenesis of Leukosis in Fowls,' respectively Dr Dean Lewis, Baltimore, President, American Medical Association, addressed the society, March 26, on "Hypothesis The Relation of Chemical Syndromes to Specific Cellular Changes"—Drs Joseph T Buxton and Landon E Stubbs, Newport, addressed the Warwick County Medical Society, Newport, on "Pulmonary Complication Following Surgical Operations" and "Pregnancy in Diabetes," respectively

GENERAL

Specialties Board to Meet in Cleveland—The recently created Advisory Board for Medical Specialties will hold its annual meeting in Cleveland, Sunday, June 10, at 6 p m, at the Hotel Cleveland Buffet supper will be served. This meeting is for the purpose of transacting general business concerning certification of specialists and also to receive applications from the special groups now engaged in the formation of new certifying boards in their respective specialties. Representatives of these boards making applications will be invited to attend. More detailed information as to requirements and procedure may be obtained on application to Dr Paul Titus, secretary, Advisory Board for Medical Specialties, 1015 Highland Building, Pittsburgh

Bequests and Donations—The following bequests and donations have recently been announced

Nathan Littauer Hospital Gloversville, N Y, \$25 000 under the will of the late Millard F Button
Ella M Brown Charitable Circle which operates Oak Lawn Hospital Marshall Mich \$48 000 by the will of George A Johnson
St Vincent's Hospital, New York, \$65 000 by the will of Margaret Crane Hurlburt
Mercy Hospital, Philadelphia, \$1 000 by the will of Hannah H Williams
Children's Hospital Philadelphia will ultimately receive the most of the \$160 000 estate of Mrs Mary V Lewis Sayres, the income to be used for maintenance
New York Hospital \$5 000 by the will of the late Helen Jay Garretson
Herman Knapp Memorial Eye Hospital New York \$20 000 and Columbia University \$10 000 for biologic research by the will of the widow of Dr Frederick Kammerer
Cancer Hospital House of Calvary Bronx N Y \$2 000 by the will of the late Dr Frederick S Dennis
University of Pennsylvania School of Medicine department of otolaryngology will receive the bulk of the \$40 000 estate of the late Dr George Fetterolf

Annual Meeting of Urologists—The American Urological Association will hold its thirty-first annual meeting at the Claridge Hotel, Atlantic City, May 22-24. Guest speakers will be Mr J Swift Joly, London, England, who will give the Ramon Gutierrez Lecture on "Etiology of Urinary Calculi" and Prof Luigi Caporale, Turin, Italy, who will speak on "Experimental Researches on Ureteral Sympathectomy." Among other speakers will be

Dr Heinrich L Wehrheim and Louis Nerb Ph D Brooklyn Bacteriophage in the Treatment of Kidney and Bladder Infections
Dr John R Cawlk St Louis Cavity Punch Operation for the Removal of Obstructive Lesions at the Vesical Orifice in Women and Children
Dr Hugh H Young Baltimore Prostatic Calculi
Dr Clyde Leroy Deming Dr Ralph H Jenkins and Gertrude van Wageningen Ph D New Haven Conn Endocrinological Relationships of Prostatic Hypertrophy
Drs Hugh Cabot Waltham Walters and Virgil S Counseller Rochester Minn Successful Plastic Operations for Hypospadias
Drs Abraham Hyman and William H Mencher New York Causes of Death Following Operations on the Urinary Tract
Dr Jose C Ferrer San Juan Puerto Rico, Filariasis of the Spermathe Cord and of the Epididymis

Sir Henry Wellcome Awarded the Remington Medal—The fourteenth Remington Honor Medal awarded by the New York Branch of the American Pharmaceutical Association

has been conferred on Sir Henry Wellcome, London. Sir Henry is a native of Wisconsin and a graduate of the Philadelphia College of Pharmacy. After establishing the firm of Burroughs-Wellcome and Company, pharmaceutical manufacturers, in London he became a British subject. He has established the Wellcome Physiological Research Laboratories, Wellcome Chemical Research Laboratories, Wellcome Historical Medical Museum, Wellcome Bureau of Scientific Research, all in London, Wellcome Tropical Research Laboratories, Gordon Memorial College, Khartoum, Africa, and the auxiliary Floating Tropical Research Laboratory on the Upper Nile. Sir Henry has also conducted ethnologic and archaeologic research. He is a member of many scientific societies in England and in 1928 received the honorary degree of doctor of laws from the University of Edinburgh. He was knighted by King George V in 1932 and has recently received the Cross of the Legion of Honor of France.

Survey of Homes for Aged—The American Trade Council, U S Board of Trade, Washington, D C, has recently made public the results of a survey of noncharitable homes for elderly persons. Twenty-eight institutions are listed in which membership may be obtained by payment of entrance fees varying from \$1,000 to \$7,000. They are independent or semi-independent and practically self supporting. The capacity of these homes varies from twenty to two hundred rooms and they are operated like clubs or American plan hotels. Some are under church auspices but admit men and women of other creeds than that of the sponsor. Five homes are listed in California, three each in New York, Wisconsin and Minnesota, two each in Oregon, Michigan, Indiana and Iowa, and one each in Nebraska, Salt Lake City, North Dakota, Pennsylvania, Washington and Massachusetts. Most of these homes are said to have been founded by some individual or group of persons in the communities in which they function. The American Trade Council offers its services to persons interested in selecting a home for their declining years, whether or not they are members. Inquiries accompanied by a stamped envelop for reply will receive attention if the seekers advise their age, physical and financial condition, and whether entrance to a home is for one person or for husband and wife. The address is 744 Jackson Place, Washington, D C.

Medical Bills in Congress—Changes in Status S 2892 has been favorably reported to the Senate, proposing to amend existing laws prohibiting the introduction of intoxicating liquor within the Indian country to permit its use as a medicine by practicing physicians for patients of Indian blood. H R 3464 has been favorably reported to the House, proposing to reimburse the Muncy Valley Private Hospital for medical treatment and hospital care of a seaman, U S Navy, who was injured while on authorized leave. The services were rendered by authority of the Bureau of Medicine and Surgery of the Navy Department but the comptroller general ruled that the government was not responsible for expenses incurred for civilian medical treatment of enlisted men of the navy and marine corps while on leave of absence. H R 6379 has passed the House, authorizing, under the Federal Emergency Public Works program, federal grants "to nondenominational educational institutions not operating for profit, which have received or are receiving public aid, for the construction, repair or improvement of any such project, or to nondenominational educational institutions not operating for profit for purposes and projects designed to serve the interests of the general public, such as hospitals in connection with class A medical schools or hospitals under public control such as municipal hospitals, for the construction, repair or improvement of any such project, but no such grant shall be in excess of 30 per centum of the cost of the labor and materials employed upon such project." **Bills Introduced** S 3560, introduced by Senator Vandenberg, Michigan, proposes to amend an act entitled "An Act to recognize the high public service rendered by Major Walter Reed and those associated with him in the discovery of the cause and means of transmission of yellow fever" so as to provide monthly payments to the father and mother of William H Dean, deceased, who "submitted to the yellow fever tests in Cuba."

Society News—The seventh annual meeting of the American Association of School Physicians will be held in Saratoga Springs, N Y, June 25-28.—The annual Conference of State and Provincial Health Authorities of North America will take place, June 5-6, in Washington, D C, followed by the Surgeon General's Conference of State and Territorial Health Officers, June 7-8.—Dr Simeon Burt Wolbach, Boston, was elected president of the American Society for Experimental Pathology at its meeting March 29, and Dr Shields Warren, Boston, was reelected secretary.—William M Clark, Ph D,

Baltimore, was named president of the American Society of Biological Chemistry at its annual meeting, March 29, Howard B. Lewis, Ph.D., Ann Arbor, was elected vice president, and Henry A. Mattill, Ph.D., Iowa City, secretary. The next annual session will be held in Detroit.—Dr. James Alexander Miller, New York, was chosen president-elect of the American College of Physicians at its annual meeting in Chicago, April 19. Vice presidents are Drs. James H. Means, Boston, Randolph Lyons, New Orleans, and James F. Churchill, San Diego. Dr. William Gerry Morgan, Washington, D. C., was reelected secretary-general, and Dr. William D. Stroud, Philadelphia, reelected treasurer.—Dr. Perry G. Goldsmith, Toronto, was chosen president of the American Laryngological, Rhinological and Otological Society at its recent annual meeting, and Dr. Robert L. Loughran, Bridgewater, Conn., reelected secretary.—Dr. Eugene L. Opie, New York, was elected president of the Society for Experimental Biology and Medicine at the recent annual meeting. Philip E. Smith, Ph.D., is vice president, and Abraham J. Goldforb, Ph.D., New York, secretary.—Dr. B. B. Vincent Lyon, Philadelphia, was elected president of the American Gastro-Enterological Association at the annual meeting in Atlantic City, April 30-May 1. Dr. Russell S. Boles, Philadelphia, was reelected secretary. Robert W. Hegner, Ph.D., Baltimore, delivered the Alvarez Lecture on "Pathogenic Protozoa in the United States."

FOREIGN

Robert Jones Prize Awarded—The British Orthopedic Association has awarded the Robert Jones Prize jointly to Mr. R. W. Butler, honorary surgeon to Addenbrooke's Hospital, Cambridge, and Mr. H. J. Seddon, resident surgeon, Royal National Orthopedic Hospital, Stanmore, for their essays on Pott's paraplegia. The award was £50 and a gold medal to each.

Institute of Hygiene and Tropical Medicine—The new building of the Belgian Institute of Hygiene and Tropical Medicine in the rue Nationale, Antwerp, including a school, library, laboratory and a research hospital with forty-eight beds, was opened, Nov. 4, 1933. It is open to all research workers and medical students. Attending the ceremony were representatives from the U. S. Public Health Service, Washington, D. C., Harvard University, Boston, the London School of Tropical Medicine, the Wellcome Bureau of Scientific Research, the Pasteur Institutes of Paris, Algiers and Dakar, and other institutions.

Government Services

U S Army Reserve Corps Needs Physicians

The Surgeon General of the U. S. Army is asking the cooperation of all class A medical schools, superintendents of approved hospitals and medical societies in an endeavor to stimulate interest in the Medical Reserve in order to bring the corps up to authorized strength. The present strength of the Medical Reserve is less than 9,000, less than half the number that would be required in the event of a mobilization. An applicant for appointment must be a citizen of the United States or the Philippine Islands, between the ages of 21 and 35, graduate of a recognized medical college, must possess a license to practice in some state, territory or the District of Columbia, must be actually engaged in the practice of medicine and must meet the physical requirements of the army. If the applicant had commissioned service in the army between April 6, 1917, and June 30, 1919, he may be appointed in any section and to any grade not above the highest grade held by him at any time, provided a vacancy exists for his grade. Original appointments are made in the grade of first lieutenant and are for a period of five years at the end of which a physician may be reappointed in his former grade or in the next higher grade, provided he has established his eligibility for promotion and a vacancy exists. Assignments are based on the officer's qualifications for the particular duty he is to perform, although due weight will be given to his desires. For promotion, the officer must have 300 hours to his credit earned during the five year period immediately preceding the date of recommendation for promotion and previous to Oct. 1, 1930 or have a certificate of capacity for the higher grade, which may be earned by passing the prescribed examination. Physicians desiring appointment should make application to the commanding general of the corps area in which they reside. Further information may be obtained from the Surgeon General, U. S. Army, Washington, D. C.

Asthma Research

The Asthma Research Council was formed in 1927 because the public, which subscribed money for investigation, was not satisfied with the fact that there was no "cure" for such a common disease. In answer to one broadcast appeal 4,000 donations, amounting to \$9,000, were received. The latest report of the council states that two factors must be borne in mind in estimating the measure of success achieved by the research workers. The ultimate problem—the discovery of a cure—must be regarded as merely the small final link in a long and intricate chain of evidence as to what are the causes of this distressing complaint. The results achieved are considered satisfactory, but funds are still needed to continue the valuable work, which moves steadily, though of necessity slowly, toward the final link in the chain. Asthma clinics are maintained at Guy's Hospital, the Hospital for Sick Children, Great Ormond Street Hospital, St. Mary's Hospital, King's College and University College, London, and the General Infirmary, Leeds. At Guy's Hospital the clinic is under the general supervision of Dr. A. F. Hurst, the senior physician who is an authority on asthma, and on its staff are a physician, two physiologists, a clinical pathologist, a biochemist and a radiologist, who work in cooperation. The physician, Dr. L. J. Witts, has published in *Guy's Hospital Gazette* an important paper on allergy and asthma, based largely on the work of the clinic. He points out that asthma is only one of a family of diseases, which includes eczema, urticaria, hay fever and certain forms of dyspepsia, dependent on sensitiveness to protein substances, such as milk, eggs and the various animal and vegetable dusts. In an analysis of 500 patients who passed through the clinic the most striking difference between the asthmatic and the normal persons were (1) the frequency of protein hypersensitiveness, as revealed by cutaneous reactions and in the personal and family history, and (2) the high incidence of morbid changes in the upper and lower respiratory tracts. Hence many hold that asthma is the result of a general factor, protein hypersensitiveness, and a local factor, damage to the respiratory tissues. But this is an incomplete explanation. As to the respiratory factor, it is generally agreed that operations on the nose produce little permanent benefit while treatment directed at the lower respiratory tract, whether inhalations, respiratory exercises or vaccines, has only a qualified success.

ALLERGY AND ASTHMA

But it is the question of allergy that Dr. Witts now discusses at length. The high incidence of other allergic diseases among asthmatic persons, the frequency of asthma or other allergic diseases in the family history, and the considerable percentage of cases of positive skin reactions have been proved beyond doubt, but little is known of the mode of development and effect of the morbid process in asthma, and in most cases corrective measures cannot be applied satisfactorily. Dr. Witts thinks that it is unfortunate that allergy should become a specialty, which in America has its exclusive practitioners and its separate journals and societies. The allergist seems to suggest that all is known about the pathogenesis and treatment of a disease when it can be shown to be associated with protein sensitivity, and he seems to regard the patient simply as an area of skin for cutaneous reactions and the injection of desensitizing agents. In no other allergic manifestation do the results of desensitization approach in success those of hay fever. Yet

with massive and expensive doses of pollen the symptoms can be ameliorated in only two thirds of the cases and complete relief given in about one third. Treatment must be repeated for several years before lasting relief is obtained. Dr Witts' experience with specific desensitization in asthma has not been encouraging.

OBSTACLES TO DESENSITIZATION

Dr Witts enumerates some of the obstacles to the view that the treatment of an allergic disease consists in discovering the substance to which the patient is sensitive and desensitizing him. 1 The multitude of potential allergens. There are innumerable proteins to which an asthmatic person may become sensitive and there is the problem of the 20 per cent of asthmatic persons in whom no skin reaction can be obtained. 2 Multiple sensitization. This was found at the Guy's Hospital asthma clinic in two thirds of the patients giving a positive skin reaction. 3 Difficulty in interpreting skin tests. The extreme variation in the percentage of asthmatic persons who give positive skin reactions by different technicians is only one difficulty. A patient may give positive reactions to substances that do not affect him clinically and negative reactions to substances that do. Pollen reactions have been observed in patients without hay fever, and negative skin reactions to pollen in patients with hay fever. Skin tests tend to persist after clinical hypersensitiveness has disappeared. Negative skin reactions are rather frequent in patients who are sensitive to food and have severe indigestion, Henoch's purpura or eczema whenever certain foods are eaten. 4 Difficulty of desensitization. Freeman and Bray attribute such failure to inadequate dosage of the offending protein but the fact remains that desensitization will always be a matter for the expert physician and the patient with plenty of time and money and will never be of much value for such a common disease as asthma. 5 Persistence of the morbid diathesis and development of new sensitizations. In asthma, single sensitization is unusual, specific desensitization is arduous, and the relief from it is rarely more than transitory. While the patient is being desensitized to one allergen, fresh sensitizations may develop. Children who are sensitive to food lose this disability and become sensitive to pollen or to dust. Cases beginning as hay fever and temporarily relieved by pollaccine develop asthma from other causes in the winter months. The final demonstration of the bankruptcy of the modern allergic hypothesis of asthma was left to van Leeuwen, who showed that asthmatic persons could live free from attacks in hermetically sealed rooms, fed with filtered air, but relapsed as soon as ordinary air was breathed. Burn has suggested that the allergic state is not due to the presence of unusual proteins in the blood but to deficiency in the amount of epinephrine circulating in the blood. Dr Witts thinks that the solution of the problem of asthma will come on biochemical lines. The similarity between the effects of histamine and the symptoms of the allergic diseases the resemblance of the action of epinephrine in asthma to proved substitution therapies, such as insulin in diabetes, and the new knowledge of the autonomic nervous system point to a promising line of attack.

A Safer Milk Supply

Sir Hilton Young, minister of health, received a deputation from the People's League of Health to urge the importance of securing a supply of clean and safe milk. Lord Moynihan said that milk was almost a perfect food but that the amount consumed in this country was much less than in many others and that there would be great advantages in increasing its consumption. Unfortunately the existing milk supply was not safe. From 3 to 15 per cent of samples were found contaminated with tubercle bacilli. Even certified milk had been found to contain them. Contaminated milk was also responsible

for the spread of other diseases, such as undulant and scarlet fever. The chief desire of the People's League of Health was to secure the eradication of tuberculosis from cattle and to obtain a supply of clean and safe milk. But the cleaning up of herds was a long process and, for the present, milk other than "certified milk" and "grade A" (tuberculin tested) milk should be pasteurized. Dr Lyle Cummins, professor of tuberculosis, Welsh National School of Medicine, said that much tuberculosis and a large proportion of tuberculous meningitis was due to milk-borne infection. It would be advantageous if the tuberculin testing of cattle could be carried out free of charge and if the several grades of milk could be replaced by one single grade of tuberculin tested milk. Dr R. C. Jewesbury, a pediatrician, said that the medical profession was no longer justified in advising the use of "raw" milk for children. It was important that pasteurization should be carefully controlled.

The minister of health, in reply, stated that he was deeply grateful to the People's League of Health for the information given by the deputation. He assured its members that they were preaching to the converted. He agreed with Lord Moynihan that it was necessary to proceed simultaneously along two lines of advance: (1) to do everything possible to remove infection from herds and (2) to take steps for the protection of milk. The government was prepared to provide a sum not exceeding \$3,750,000 in aid of a campaign for securing a purer milk supply. The importance of educating the public with regard to the milk supply was great and in this task the People's League of Health could be of the greatest assistance.

PARIS

(From Our Regular Correspondent)

March 28, 1934

Goiter in France

At its last trimonthly session, held in Paris, the *Assemblée de la médecine générale française* discussed the documents submitted by practitioners from all the departments of France, on the subject of goiter. This is what was found. There is a general retrogression of the epidemic related to the improvement in hygiene and in drinking water. There are still permanent regional foci in the Vosges, the Jura, Alsace, the Alps and the Pyrenees. In Auvergne the endemia has retrogressed to such an extent that it is confined to families with hereditary thyroid disease. Goiter is sporadic (the Loire basin) and rare in departments along the coast (including Corsica) and in the plains in general. It is almost unknown in the departments of Nord and Pas-de-Calais. Cretinism, which was frequently observed in association with goiter, receives today little attention. On the contrary, the rural physicians reported that one finds small nodular goiters almost everywhere (particularly in Sarthe, Eure-et-Loir and Var). In the large cities, most of the small goiters are imported. Inquiry reveals frankly the existence of unsuspected foci in villages in some departments regarded as goitrogenic or otherwise. Observation of the stable population of these goitrogenic burghs directs attention to various factors, particularly the drinking water under many different forms: iron-containing water (not only in Sarthe but also in Cher), copper-containing water (in Puy-de-Dôme), noncalcareous water (Lot, Charente, Corse), shallow water easily polluted (Haut-Rhin, Pyrenees-Orientales, Lot) and well water highly mineralized owing to passage through alluvial deposits—sometimes bacterial (Sarthe, Seine-et-Oise, Pyrenees-Orientales, Haut-Rhin). The endemia in these foci often ceases with the introduction of different drinking water (even though from goitrogenic regions: Alpes-Maritimes, Puy-de-Dôme, Hautes-Pyrenees). Retrogression of goiter has been shown to be in direct relation with the enrichment of the diet and the introduction of a greater variety of foods, notably with the use of

sea foods (Puy-de-Dome), the discarding of an almost exclusively vegetarian diet and the introduction of more meat (Dordogne, Alpes-Maritimes) and the addition of wine to the water (Basses-Pyrenees). The influence of heredity has often been noted—on the female side in 40 per cent of the cases. Exophthalmic goiter is, on the whole, more frequent in the cities than in the rural districts. There are also regional sectors (Eure-et-Loire, Sarthe, Bouches-du-Rhone). On the other hand, vast regions are spared. Exophthalmic goiter is exceptional in agricultural regions such as Loiret, Cotes du-Nord and Var, and in industrial regions such as Valenciennes, whereas the coast regions are more affected (Pas-de-Calais, Loire-Inferieure). Farmers have been more frequently attacked since the war (Doubs, Dordogne). In association with this condition, the practitioners often observe high emotions at various periods in the sex life of the woman. They point out also the determining role of infections: acute articular rheumatism, infections of adolescents, typhoid and, in general, intestinal infections of water origin. They emphasize the relations between the hyperthyreoses and tuberculosis and conclude that hyperthyroidism is not a factor of aggravation but, on the contrary, of resistance in the tuberculous person. The amelioration of exophthalmic goiter in a tuberculous person is sometimes followed by recrudescence of pulmonary tuberculosis. The treatment of hyperthyreoses, according to the general belief, should be chiefly medical. Combined with ordinary medical treatment, rest, possibly even isolation is useful and sometimes sufficient. Physical therapy, especially radiotherapy and electrotherapy, associated with medical treatment, is being used more and more. Owing to the refinements in the technic, thyroid surgery is becoming more common as a special type of surgery. But in many departments of France it is not readily accepted.

The Identity of Various Forms of Scarlet Fever

La Societe des medecins des hopitaux de Paris discussed recently, at length, the subject of "The Identity of Various Forms of Scarlet Fever," the unanimous conclusion being that medical, puerperal and surgical scarlet fever are produced by the same micro organism. A Lemierre and Jean Bernard adduced proof with respect to puerperal scarlet fever, with the aid of twenty-three observations collected from their department in the Hopital Claude-Bernard. The cutaneous exanthem was that of the typical case of scarlet fever, with a somewhat greater frequency than usual of miliary vesiculation. Three persons died, one with a syndrome of malignant scarlet fever and one with streptococcemia. Four infants hospitalized with their mother died: one from bronchopneumonia, one from streptococcal septicemia and two from erysipelas. Puerperal scarlet fever is therefore true scarlet fever, with a peculiar frequency of streptococcal manifestations. Robert Debre, G. Ramon, Maurice Lamy and Burnet found in the lochia hemolytic streptococci, with which they were easily able to produce a toxin similar to the Dick toxin, whereas the throat of the patient did not contain any hemolytic streptococci. In the ward in which the puerperal scarlet fever patients were located, an intern and a nurse contracted the disease, while a second intern developed erysipelas. They injected into the children a streptococcus toxin as a prophylactic measure, but it still had a pathologic potency, for a typical case of scarlet fever developed suddenly, with vomiting, swelling and redness of the throat and tongue just as in ordinary scarlet fever.

Concerning surgical scarlet fever, Lemierre and Flandrin reported two cases observed after appendicectomy. The Schultz-Charlton test was positive. The scarlet fever antitoxin does not appear to have convincing results. Mr. Halle, who had observed previously at the Hopital des enfants malades numerous cases of postoperative scarlet fever with frightful sequels (intestinal gangrene, gangrene of the penis after circumcision) confirmed

that the malignancy of this form of scarlet fever had certainly diminished. He obtained excellent results from the use of convalescent serum. It is not necessary to exceed doses of from 10 to 20 cc.

Disturbance at the University of Paris

A recent ministerial decree changed the makeup of the council on discipline at the university. These councils consist of members elected by the students, but foreign students are seldom chosen, unless some foreign student is involved. Some fifty foreign students recently staged a demonstration before the university as a protest against what they regarded as an injustice. The disturbance was carried to the court of the Faculte de medecine, where a serious row occurred. Four students were injured and had to be given first aid before they were taken home by the police. The Association general des etudiants, which was about to hold its annual election of members to serve on its committee, was unable to convene, owing to the general excitement that prevailed as a result of this incident. The election was postponed until a later date, the old committee continuing to serve ad interim.

BERLIN

(From Our Regular Correspondent)

March 26, 1934

Consultation Centers for Expectant Mothers

Centers for expectant mothers and for infants have existed for many years in nearly all the larger cities of Germany, but it is planned to make such aid more extensive than it has been. In 1933 in the seventy cities of more than 50,000 inhabitants there were sixty-three consultation centers for expectant mothers. In thirty-three of these cities there was only one consultation center which does not seem adequate. In two cities there were from six to ten centers, in five cities, from eleven to thirty, and in three cities, more than thirty. Berlin, with forty-six centers, had the largest number.

Thirty-two cities report on the number of examinations made in their consultation centers. In 1933, a total of 34,700 examinations were carried out, almost exclusively by physicians and 76 per cent of them were first examinations, that is, the majority of the women dispensed with a more frequent consultation and were content with the first definite diagnosis of pregnancy.

Welfare aid for expectant mothers and puerperants was granted in eighty-five cities. Forty-one cities grant maternity aid if the income of the family does not exceed from one to one and a half times the regular amount granted for general welfare aid. Five cities grant maternity aid even though the family income is equal to from two and a half to three times the usual amount allowed for welfare aid. Twenty-seven cities come to the aid of expectant mothers when the *krankenkasse* refuses aid. Other cities base maternity aid on still different criteria.

The period for which maternity aid is granted varies. In most cities (63 per cent) it is granted for ten weeks. Twenty-seven cities grant aid for an even longer time. In thirteen cities maternity aid is allowed up to twelve weeks. In fourteen cities for a period of sixteen weeks, and occasionally even longer. Only in thirty-nine out of eighty-two cities is mention made of a course of instruction for expectant mothers.

Infant welfare aid is organized on a much wider basis than maternity aid. Ninety cities have infant aid centers. The expense is borne in most cases by the city alone. In the cities covered by the report there were only 338 maternity consultation centers all told, whereas there were 922 infant consultation centers. The city of Berlin alone reports eighty-three. But not only the number of infant welfare centers is greater,

their facilities are used much more frequently and regularly. In the year under consideration, 104,550 consultations were given in the cities with more than 200,000, 48,230 consultations in the group of cities with from 100,000 to 200,000 population, and about 48,000 consultations in the cities with from 50,000 to 100,000 population. The total number of consultations was 197,660, or more than five times as many as in the maternity consultation centers. In contrast with the maternity centers, the infant welfare centers were visited usually more than once. In the latter, only 48 per cent (less than one half) of the consultations were first consultations, whereas in the maternity consultation centers 76 per cent of all cases were first consultations.

The wider utilization of the infant consultation centers is due mainly to the fact that securing the clientele is simple, as it is effected through the notification of births at the office of the registrar.

Reorganization of Scientific Societies

The *Versammlungen Deutscher Naturforscher und Aerzte*, as it has existed for more than a generation has adopted a new order of business and a new constitution. The object of the new organization is to oppose the splitting up of medicine and the natural sciences into various specialties. It is proposed to emphasize the problems in which all (or at least many) branches of natural science and medicine have a common interest. At the same time, the traditional task of the society must not be forgotten, namely, to give the public an insight into the growth of German science.

The general assembly will be held only once in two years, which will necessitate using great care in the choice of topics and in applying sharp criticism to the subject matter to be presented. The scientific section as such will cover three and one-half days at the most. The board of trustees will henceforth organize only general sessions, sessions of the main scientific and medical groups, and joint sessions of several branches but no sessions of single branches. In addition, there will be evening lectures on popular scientific subjects. The topics for all sessions will be decided on by the officers of the society after consultation with the "scientific committee" and, as far as possible, with the large scientific societies representing individual specialties. In the general sessions and the sessions of the main group, scientific questions will be discussed that have either reached a reasonably definite settlement or that present a high degree of general interest. As speakers, such investigators will be chosen as have shown special merit in the fields concerned. In the opinion of the officers of the society, a general discussion the course of which no one can foresee would weaken the force of these communications and lessen the effect on the world's scientific circles; hence all discussion will be reserved for the so-called joint sessions, which will deal with topics that are of interest to the representatives of at least several of the branches of natural science or medicine and that will be presented by several speakers in the form of concise papers, to be followed by a detailed thorough discussion. In these sessions particularly the principle of combining several problems of common interest will come to the fore.

The officers of the society will not organize any professional meetings for the discussion of topics pertaining to a single branch of science or medicine. It is expressly stated that there is no place in the *Versammlungen Deutscher Naturforscher und Aerzte* for those persons who have no interest in anything outside their own specialty. Furthermore, no "unofficial" sessions of representatives of specialties will be allowed to disturb or take time away from the regular program as announced. Affiliated societies representing specialties will however be permitted to hold sessions in the convention city immediately before or immediately after the regular sessions.

The endeavors of the aforementioned society to emphasize the solidarity of the natural sciences and the medical sciences will likewise be furthered by the *Zweckverband der Deutschen naturwissenschaftlichen und medizinischen Kongresse*. The declared objective of this league is to create sentiment that will make for a broader organization of congresses of specialists. The propaganda will be confined to a publicity campaign and will not include any attempts to exert an immediate influence on the several societies of specialists. It is hoped that, in this manner, greater coherence will be injected into the organization of German scientific congresses as a whole.

Research on Hemostasis Following Injuries

Professor Magnus, the new occupant of a chair of surgery at the University of Berlin addressed the Berlin Medical Society on "The Peripheral Vascular System." In his research he has been concerned with the questions: How does the peripheral vascular system react to local stimuli? and Can hemostasis be made accessible to direct observation? He found capillary microscopy applied to the nail groove the most useful available method. If one injured with a needle a capillary loop in the nail groove of the human hand, an intensive hemorrhage was always produced that flooded the whole area. By producing an ischemia with an Esmarch bandage one was able to observe that the arterial system emptied its whole contents into the venous system. Because of the comparatively rude setup of the experiment and the difficulty of maintaining a bloodless condition for any length of time, by reason of the severe pain, no great progress was made by this method. Not until Magnus used the Peterfisch micromanipulator, with which he was able to cut into a sharply circumscribed spot in a capillary loop under direct vision, was his research successful. The method followed was this. In an experiment on himself he produced an ischemia in the left hand, which was enclosed in a plaster cast. A certain spot in the capillary network was selected, which was then injured and observations were instituted over a considerable period.

Is hemostasis brought about after injuries effected by contraction of the arteries or by thrombosis? Clinical observations point rather to contraction, otherwise it would be difficult to understand, when whole extremities are shot or torn off, that not infrequently one finds the stump of a vessel that is not bleeding. This observation is old, and again and again in medical history there have been periods in which artificial ligation of injuries was strongly advised against. The bleeding vessel was closed a while with the finger until it contracted, then the bleeding stopped definitively. Magnus confirmed this experimentally, while his assistant was preparing the soft parts in a lower leg amputation, he exposed the whole popliteal artery, together with its branches, and ligated it at the terminals. At first the blood was propelled rapidly to the point of ligation, but a gradual contraction was plainly recognizable, and finally the contraction became so complete that transverse incisions of the vessel without lumen could be observed. Nowhere could an obstructing thrombus be found.

Experimental injuries of the capillary loop with the micromanipulator confirm these macroscopic observations. In the film it can be noted that the vascular loop, filled originally in a normal manner with blood, undergoes a maximal contraction after the injury, becomes bloodless and is then invisible. The injured capillary perishes, as later examination reveals, and is not reformed at the same site. Future vascularization is taken over by adjacent vessels or by vessels coming forward from the deeper tissues. It appears to be proved that hemostasis following an injury does not result, as was for a long time assumed through the formation of thrombi in the vessels, but that the vessels have the capacity to prevent bleeding by contraction of the walls.

Black Cardiacs

Ayerza described in a lecture delivered in 1901 the clinical picture of a condition known only through his school, since the original lecture was not published. Some patients having chronic bronchial diseases come to have an intense cyanosis followed by symptoms of cardiac insufficiency. The author called these patients "black cardiacs" because of the disproportion which exists between the comparatively mild cardiac symptoms and the intense cyanosis. Dr. M. R. Castex and his collaborators have lately studied this clinical picture. The disease, which develops in three stages, bronchial, pulmonary and cardiac, is most common in man. It starts with recurrent bronchitis, usually during winter. Then the pulmonary or bronchopulmonary stage appears, with emphysema, sclerosis of the pulmonary artery and cyanosis due to insufficient oxygenation in the alveoli. There is also an increase of the alkali reserve, polyglobulism, hyperviscosity, apathy, somnolence and capillary dilatation. Cardiac insufficiency appears in the third stage of the disease. The sclerotic lesions of the pulmonary artery are secondary to hypertension in the lesser circulation. These lesions may exist without the presence of cyanosis. Their coexistence accelerates the evolution of the third stage.

Rôle of Pancreas and Suprarenals in Formation of Muscular Glycogen

Foglia, Damborsi, Fernandez and Leloir recently reported before the Sociedad Argentina de Biología the results of studies of the rôle of the endocrine glands in the reconstitution of the muscular glycogen. After removal of the suprarenals, the hepatic glycogen rapidly decreases while the muscular glycogen is still normal within minimal limits forty-eight hours later. Following pancreatectomy the capacity both to resynthesize glycogen after fatigue and to form it after the intravenous injection of 2 Gm of dextrose per kilogram of body weight fails. The previous injection of suprarenal extract gives suprarenalectomized animals the capacity of forming muscular glycogen and generally they produce it in supernormal amounts. The pancreas has a similar action. The values for muscular glycogen are slightly reduced forty-eight hours after pancreatectomy, but the glycogen is not resynthesized after fatigue, as in normal animals, nor is it deposited in the muscles after the injection of dextrose in the veins. However if insulin is injected, the capacity to resynthesize and deposit glycogen in the muscles is newly developed. The same glycogenic functions are observed by uniting the carotid artery and jugular vein of a suprarenalectomized dog to the artery and veins of an isolated or grafted pancreas. This proves that insulin regulates the capacity of resynthetization and deposition of glycogen independent of the nervous system. After the vagus nerves of chloralized dogs and cats have been cut, both the resynthesis and the deposition of muscular glycogen remain normal. This is contrary to the opinions of Hoet, Ernould and Debois, who claimed that the resynthetization and fixation of muscular glycogen are functions of the vagus nerves and that if these nerves were cut there would not be any secretion of insulin. The liver has no specific hormonal rôle.

Fifth National Congress of Medicine

The fifth National Congress of Medicine will take place in the Faculty of Medicine and Hospital Centenario of the city of Rosario, September 4-11. Dr. C. Munagurria is president and Drs. M. Vignoles, P. R. Omnes and J. Recalde Cuestas secretaries. The official topic to be discussed is amebiasis with the following speakers: Drs. M. R. Castex and D. Greenwax

on parasitology and clinical medicine, D. Staffieri, on extra intestinal localizations, S. Mazza, on its epidemiology, and A. Marotta, on its surgical treatment. There will be eighteen sections, each with its own topics to be discussed.

ITALY

(From Our Regular Correspondent)

Feb. 28, 1934

Congress of Dermatology and Syphilology

At the twenty-eighth Congress of Dermatology and Syphilology, held in Pavia under the chairmanship of Professor Mantegazza, the first topic was physiopathology of the skin in relation to newer data of morphologic and physicochemical research. The subject was discussed by speakers from various Italian clinics.

Professor Tommasi of the Clinica di Palermo, who spoke on the physiology of the skin in relation to the neuroendocrine system, emphasized that the skin is under the special control of the sympathetic, but a parasympathetic innervation has been demonstrated. The skin is the site where the external stimuli have their greatest effect on the neurovegetative system which explains many physiopathologic happenings and is useful from the therapeutic point of view when one desires to influence the general vegetative tonus and the whole organism. The skin does not have a metasympathetic system (peripheral and autonomic ganglions) as do the viscera. The vegetative regulation of the skin of the face is independent of that of the remainder of the body but is more closely connected with the superior centers which coordinate the higher functions. The bulbar vasodilatory center of the face is close to that of the gastromotor which explains certain physiologic and clinical facts. Tommasi does not admit that the skin is a hormone producing organ. The skin, however, produces various ferments and immunizing substances. There is a hormone equilibrium peculiar to every person to which, if artificially disturbed, he tends to return. The neuroendocrine factor has great importance in dermatology and must always be regarded as present. It can not, however, be regarded as a direct cause of any isolated dermatologic disorder properly so called. The speaker brought out the importance of this method of considering the diagnosis and treatment of dermatologic problems. The correction of the terrain with reference to exogenous causes, reducing the local sensitivity, and the removal of the irritative causes through a knowledge of the various reflexes, even of distant organs.

The second topic concerned lesions of the joints and bones in syphilis. The speaker, Professor Casazza, brought out the following conclusions. Skeletal changes of syphilitic origin are still numerous and complex. Congenital syphilis of the bones is a clinical entity. In addition to many types caused directly by the spirochete there are skeletal changes in which the action of syphilis is indirect, constituting a dystrophic cause affecting the bones. In regard to clinical observations, various points merit attention. Many syphilitic bone lesions show few signs of their existence or are concealed under obscure symptoms.

Radiology is a useful means of diagnosis. Serologic tests have value, but in certain periods and types of skeletal lesions they may be negative. The therapy of today comprises many methods of treatment, by the proper use of which rapid results may be secured, save in exceptional cases such as tabetic arthropathies.

Several further communications were offered. Hoffmann of Bonn spoke on the rapid diagnosis of recent syphilis (also primary) by means of smears from the tonsils.

The congress awarded the de Amicis prize to Prof. Mario Artom of Verona for his work on "Blood Accidents Due to Arsphenamines."

The assembly passed a resolution, to be presented to the Direzione generale di sanità pubblica, concerning the prophylaxis against syphilis, and the various serologic methods recently proposed

Prof Ludovico Tommiasi, clinician of the University of Palermo, was chosen president of the Consiglio direttivo della Società italiana di dermatologia e sifilografia

Professor Tanzi

Prof Eugenio Tanzi, occupant of the chair of clinical psychiatry at the University of Florence, died recently at Salo. His first works on paranoia and delinquency opened the way to a university chair. After serving as assistant in the Clinica psichiatrica, he entered the Istituto di fisiologia in Florence. He obtained then the chair of psychiatry in the University of Florence, and his first task was to organize the clinic of San Salvi. He founded the *Rivista di patologia nervosa e mentale*, which is now in its thirty-eighth year. Of his numerous publications on psychiatry, those concerning a new theory on hallucination are frequently cited. In addition to *Psichiatria forense*, he published in collaboration with Lugaro, a treatise on mental diseases, which is now in its third edition. In Florence Tanzi founded his school, whose pupils are to be found in many universities and psychiatric hospitals of Italy.

The Experimental Radio-Electric Center

Under the supervision of the minister of public education, an experimental radio-electric center has been established in Rome for the purpose of carrying on research. The center will study also the transmission and reception of electromagnetic waves.

Anthropometric Research

Dr Scatameccia reported recently to the Società di medicina legale in Rome the anthropometric measurements he secured from examining ninety-one cadavers of young men in connection with the determination of the constitutional type of Viola and of Barbara. Forty-two were found to be longilineal and forty-nine were brevilineal. In previous research the speaker had found few relationships between the dimensions and form of the cranium, on the one hand and the "habitus," on the other hand. In his present research the speaker found no relation between the total size of the cranial region and the facial region, on the one hand, and that of other parts of the body. In the individual dimensions, the length of the cranial and facial regions agreed with the development of the limbs, and the width of the cranial and facial regions agreed with the width of the trunk and its segments. The form of both sections of the head with respect to various norms did not present any relation to that of the trunk and its parts. The speaker confirmed the views advanced by Professor Ottolenghi with respect to the accuracy of the alleged functional morphology on which Barbara based his classification of types of cranium, namely, that the cranial region follows the development of the limbs, and the facial region the development of the trunk.

Marriages

FRANCIS CURTIS DOHAN, Philadelphia, to Miss Marie Barbara Postenrieder of Mering, Germany, March 28

JAMES FRED TERRY, Cookeville, Tenn., to Miss Margaret Katherine Harris of Union City, recently

DUDLEY CURTIS ASHTON to Miss Myrtle Irene Cooper, both of Richmond Va., April 3

FLORANCE L. SULLIVAN, Freeport, Ill., to Miss Magdalen Heim of Chicago, April 5

ERNEST K. McCOWN, Stanfield, Ore., to Miss Beth McKay of Scappoose, April 19

Deaths

Benjamin Franklin Van Meter, Lexington, Ky., Bellevue Hospital Medical College, 1897, in 1910 member of the House of Delegates of the American Medical Association, member of the Kentucky State Medical Association, veteran of the Spanish-American and World wars, fellow of the American College of Surgeons, on the staffs of St. Joseph's and Good Samaritan hospitals, aged 60, died, March 8, in Rancho Santa Fe, Calif., of pulmonary tuberculosis.

Albert Ware Nash, Dallas, Texas, Vanderbilt University School of Medicine, Nashville, Tenn., 1906, member of the State Medical Association of Texas, fellow of the American College of Surgeons, formerly city health officer, served during the World War, member of the visiting surgical staff of the Parkland, Dallas Methodist and St. Paul's hospitals, on the courtesy staff of the Baylor Hospital, aged 50, died, March 11, of coronary thrombosis.

Harry Louis Abramson, St. John, N. B., Canada, Yale University School of Medicine, New Haven, Conn., 1911, chief of laboratories, New Brunswick Department of Health, member of the board of professional examiners of the Council of Physicians and Surgeons of New Brunswick, on the staff of St. John General Hospital, aged 48, died, April 17, in the Hospital of the Rockefeller Institute, New York.

Ernst Jonas St. Louis, Medizinische Fakultät der Friedrich-Wilhelms-Universität, Berlin, Prussia, 1895, member of the Southern Surgical Association and fellow of the American College of Surgeons, on the staffs of the Jewish Hospital, St. Louis City Hospital, Jewish Home for Chronic Invalids and St. John's Hospital, aged 61, died, March 2, when he jumped from a seventeen story window.

Chauncey Boyd Griffiths, Newark, N. J., Columbia University College of Physicians and Surgeons, New York, 1896, member of the Medical Society of New Jersey, fellow of the American College of Surgeons, aged 64, on the staff of the Hospital for Women and Children where he died, March 23, of carcinoma of the bladder and diabetes mellitus.

Roscoe Conkling Hubbard, Tampa, Fla., Mississippi Medical College, Meridian, 1912, past president of the Hillsborough County Medical Society, served during the World War, formerly mayor of Bushnell, aged 48, died, March 24, in the Veterans' Administration Facility, Seminole, of cerebral embolism and gangrene of the left leg.

Paul Lovejoy Holliday, Athens, Ga., University of Georgia Medical Department, Augusta, 1917, member of the Medical Association of Georgia, past president of the Clarke County Medical Society, served during the World War, on the staff of the Athens General Hospital, aged 41, died, April 22, of heart disease.

Oakey Stitt Gribble, Clarksburg, W. Va., University of Maryland School of Medicine, Baltimore, 1904, member of the West Virginia State Medical Association, served during the World War, formerly superintendent of the Mason Hospital, aged 57, died, April 3, of carcinoma of the prostate with metastasis.

Levi R. Wilhelm, Blanca, Colo., Eclectic Medical University, Kansas City, Mo., 1901, Hahnemann Medical College of the Kansas City University, 1902, county coroner, registrar of vital statistics, county physician and city health officer, aged 68, died March 25, in the Lutheran Hospital, Alamosa, of heart disease.

DeWitt Clinton Huntoon Waterloo, Iowa, Rush Medical College, Chicago, 1903, past president of the Black Hawk County Medical Society, formerly police commissioner and health officer, on the staffs of the Allen Memorial and St. Francis hospitals, aged 61, died, April 17, of cerebral hemorrhage.

Edward B. Wiley, Grinnell, Iowa, Hahnemann Medical College of Philadelphia, 1882, member of the Iowa State Medical Society, formerly member of the city council and mayor, on the staffs of the Grinnell Community Hospital and St. Francis Hospital, aged 76, died, March 5, of abdominal tumor.

Jacob W. Graybill Newton, Kan., College of Physicians and Surgeons, Medical Department, Kansas City University, 1898, formerly county health officer, lieutenant governor and state senator, aged 62, died, March 24, in the Junction City (Kan.) Municipal Hospital, of pneumonia.

Aden Clarence Gates Kingston, N. Y., Albany Medical College, 1893, on the staffs of the Kingston and Benedictine hospitals and formerly on the staff of the Ulster County

Tuberculosis Hospital, aged 72, died April 8, of coronary thrombosis and coronary sclerosis

Warren Buxton Stone ☉ Schenectady, N Y, Harvard University Medical School, Boston, 1899, fellow of the American College of Physicians, member of the American Society of Clinical Pathologists, aged 57, died, March 31, of cerebral hemorrhage and arteriosclerosis

Ernest Linwood Hill, Framingham, Mass, Dartmouth Medical School, Hanover, N H, 1902, member of the Massachusetts Medical Society, served during the World War, on the staff of the Framingham Union Hospital, aged 55, died, April 1, of heart disease

William Edward Hendry ☉ Willimantic, Conn, Albany (N Y) Medical College, 1898, past president of the Windham County Medical Society, on the staff of the Windham Community Memorial Hospital, aged 60, died, March 11, of coronary thrombosis

Charles Stewart Houghland, Milroy, Ind, Marion-Sims College of Medicine, St Louis, 1892, member of the Indiana State Medical Association, served during the World War, aged 62, died, April 15, in St Vincent's Hospital, Indianapolis, of heart disease

Joseph Peter Bouvier ☉ Whitinsville, Mass, School of Medicine and Surgery of Montreal, Faculty of Medicine of the University of Laval at Montreal, Que, Canada, 1905, aged 53, died, April 2, in the Woonsocket (R I) Hospital, of heart disease

David Roy Nelson, Moline, Ill, Northwestern University Medical School, Chicago, 1908, past president of the Rock Island County Medical Society, formerly coroner of Johnson County, Wyo, aged 55, died suddenly, April 2, of heart disease

Charles Alexander McLelland, Keyes, Okla, Eclectic Medical University, Kansas City, Mo, 1901, Barnes Medical College, St Louis, 1910, aged 57, died, January 26, of pulmonary tuberculosis, chronic nephritis and carcinoma of the stomach

Robert Connery O'Neil ☉ Providence, R I, Medical College of Virginia, Richmond, 1925, on the staffs of the Memorial Hospital, Pawtucket, and the Hope and Charles V Chapin hospitals, aged 34, died, March 21, of lobar pneumonia

Walter Milton Babb ☉ Keyser, W Va, University of Pennsylvania School of Medicine, Philadelphia, 1893, past president of the West Virginia Public Health Council on the staff of the Potomac Valley Hospital, aged 63, died, March 25

William Sprague Sherman, Newport, R I, Jefferson Medical College of Philadelphia, 1888, member of the Rhode Island Medical Society, past president of the Newport County Medical Society, aged 72, died, February 28, of heart disease

George Francisco Simpson, Louisville, Ky, University of Louisville School of Medicine 1881 member of the Kentucky State Medical Association, member of the board of education for twenty years, aged 74, died March 26, of bronchopneumonia

Jonas Lester Johnson, Eastland, Texas Tulane University of Louisiana Medical Department, New Orleans, 1897, formerly county health officer, aged 64, died, January 17, of peritonitis, following perforation of the urinary bladder

Joseph Frank Hackett, Detroit, University of Michigan Medical School, Ann Arbor, 1924, on the staff of the Herman Kiefer Hospital, aged 35, died, April 10, in the Harper Hospital, of hypertension chronic nephritis and uremia

James Maxwell Hobson, Belton, S C, Medical College of the State of South Carolina, Charleston, 1913, member of the South Carolina Medical Association, aged 53, died April 6, of a self inflicted bullet wound

James Noble Garber, Detroit, Detroit College of Medicine, 1907, member of the Michigan State Medical Society, aged 65, died, April 7, in the Grace Hospital, of uremia and hypertensive cardiorenal disease

John William Reynolds, Creston, Iowa, Kansas City (Mo) Medical College 1898, chairman of the state board of assessment and review, formerly mayor, aged 59, died, March 14, at Detroit, of myocarditis

Richard L Barrington, Washington D C, Georgetown University School of Medicine, Washington, 1889, aged 69, died suddenly April 3 in the Missouri Baptist Hospital, St Louis of heart disease

George Edward Albon, Groton, N Y, Niagara University Medical Department, Buffalo 1894, member of the Medical Society of the State of New York, aged 69, died, January 25 of hypernephroma

Charles Lafayette Williams ☉ Greensburg, Ind, College of Physicians and Surgeons of Chicago, School of Medicine of the University of Illinois, 1903, aged 70, died, March 10, of coronary thrombosis

Olin A Williams ☉ Butler, Pa, Hahnemann Medical College and Hospital, Chicago, 1890, past president of the Butler County Medical Society, aged 75, died, March 29, of coronary thrombosis

Clarence E Huston ☉ Paulding, Ohio, Medical College of Ohio, Cincinnati, 1893, president of the Paulding County Medical Society, county health officer, aged 65, died, April 14, of heart disease

Thomas Francis Burnett, Ridgewood, N J, Bellevue Hospital Medical College, New York, 1893, member of the Medical Society of New Jersey, aged 64, died, April 2, of bronchopneumonia

James E Cooper ☉ Cameron, W Va, Starling Medical College, Columbus, 1897, aged 59, died, April 15, of injuries received when the automobile in which he was driving was struck by a train

Peter E Wilkin, Colquitt, Ga, College of Physicians and Surgeons, Baltimore, 1890, formerly mayor of Colquitt, and member of the state legislature, aged 67, died, February 27, of endocarditis

Walter Charles Brady, Slatetale, Pa, Jefferson Medical College of Philadelphia, 1912, member of the Medical Society of the State of Pennsylvania, aged 52, died, April 11, of myocarditis

John Adams Barnette ☉ Watertown, N Y, University of Michigan Medical School, Ann Arbor, 1890, on the staff of the Mercy Hospital, aged 65, died, April 4, of cerebral hemorrhage

Edwin B Ellis, Streetman, Texas, Gate City Medical College, Dallas, 1907, aged 62, died, January 19, in a hospital at Corsicana, as the result of injuries received in an automobile accident

Wilson Alpheus Smart, Clayton, Ala, Louisville (Ky) Medical College, 1884, member of the Medical Association of the State of Alabama, aged 72, died, April 1, of heart disease

James Edgar Studebaker, Urbana, Ohio, Pulte Medical College, Cincinnati, 1879, aged 77, died, March 7, in a hospital at Dayton, of diabetes mellitus and abscess of the lung

Edward Maximilian Weiss, San Francisco, University of California Medical Department, 1877, aged 78, died, March 23, of a cardiac wound self inflicted with a surgical instrument

Charles J Barrett, Pittston, Pa, Columbian University Medical Department, Washington, D C, 1887, aged 71, died April 1, in the Pittston Hospital, of injuries received in a fall

Horace Ward Sheldon, Berkeley, Calif, Rush Medical College Chicago, 1885, aged 79, died, March 12, in the Alta Bates Hospital, of cerebral hemorrhage and arteriosclerosis

Louis Gustav Wille, New Braunfels, Texas, Tulane University of Louisiana Medical Department, New Orleans, 1892, aged 70, died, February 4, of cerebral hemorrhage

William W Buck, Rural Retreat, Va, College of Physicians and Surgeons, Baltimore, 1885, aged 77, died, March 25, of heart disease and nephritis

Marion P Willis, Commerce, Okla, Kentucky University Medical Department, Louisville, 1903, aged 64, died, February 1, of uremia and nephritis

Mervin Rives, Houston, Texas, University of Nashville (Tenn) Medical Department, 1898, aged 58, died, March 27, of acute dilatation of the heart

William Francis Hoeler ☉ Newark, N J, Maryland Medical College, Baltimore, 1908, aged 53, died suddenly April 8, of heart disease

George Herman Jennings ☉ Jewett City, Conn, Long Island College Hospital, Brooklyn, 1875, aged 83, died, March 4, of lobar pneumonia

Clark Mathew Proctor, Ames Iowa, Rush Medical College, Chicago, 1897, aged 61, died, February 3, of angina pectoris

Vincent Burgess, Greene, N Y, Kentucky School of Medicine, Louisville, 1876, aged 83, died March 24, of senile debility

Edwin O Hyde, Prineville Ore, American Health College, Cincinnati, 1880, aged 84, died, March 19, of heart disease

Samuel Aydelotte Billing, New Orleans, Bellevue Hospital Medical College, New York, 1897, aged 57, died March 2

Bureau of Investigation

IRONIZED YEAST

A "Patent Medicine" of the Get-Plump-Quick Type

The public has been made what the advertising men would call "yeast conscious" by the extensive and intensive advertising of the Fleischmann product. The food faddists have harped for years on the theme that most of us are suffering from an iron deficiency. The facts are, of course, that as a medicine yeast has no important place except as a means of furnishing vitamin B, which ordinarily should be and would better be obtained from one's food. As for a deficiency of iron, the average American dietary, rich as it is in meat, should make such a deficiency unnecessary if not improbable. But the public is not aware of these facts so that it is not surprising that, by plausible advertising, a "patent medicine" called Ironized Yeast has been built up into one of the best sellers in the nostrum field.

Ironized Yeast advertising is typical of the times. It plays on, and tends to create, an inferiority complex. The young woman with angular lines is led to believe that what she needs in order to obtain or retain the admiration of the opposite sex is to take Ironized Yeast. The concern that puts out Ironized Yeast has issued an advertising broadside of the tabloid newspaper type called *News Pictorial*, it is a sixteen-page affair profusely illustrated. In this we find articles bearing such captions as "What Kind of Women Do Men Stay in Love With?", "Husband-Stealer Beaten at Her Own Game—Wife Gets Wise to Herself in the Nick of Time—How She Won Her Man Back for Keeps", "Skinny Spouse Told Must Figure Out Love Tangle—Court OK's Hubby's Eyes for Curves", "Real He-Men Pick 'em Plump."

The *News Pictorial* also features a "short short story" One, entitled "Was It Love or Sex?" dealt with the sad case of skinny Lina, who, on the day before she was to marry Roy, found him making love to her room-mate, Norma. The reason, of course, was that Norma had curves and Lina hadn't. Following the taking of Ironized Yeast, however, Lina developed the Mae West figure and everything was lovely. Another *News Pictorial* story of the same type was entitled "Was Her One Mistake A Sin?" Here the angular young wife finds her husband making love to her more buxom sister, so she goes home to mother, who naturally advises her to take Ironized Yeast! The skinniness disappears, "And now—thanks to Ironized Yeast—Fred and I are the happiest couple in the world."

It is a rather tragic commentary on our boasted civilization that this sort of stuff can sell anything, but it evidently does. In the newspaper advertising of Ironized Yeast, skinny versus well developed men and angular versus well-curved women are brought into juxtaposition with the object of showing how necessary a rounded figure—and therefore Ironized Yeast—is to achieve economic or social success or marital happiness. In connection with some of the earlier illustrated advertisements, the Federal Trade Commission has expressed its opinion. In 1931 the Commission filed a complaint against J G Dodson of Atlanta, trading under the name of the Ironized Yeast Company. After calling attention to the fact that the Ironized Yeast advertisements claim that the product will clear the complexion, purify the blood, increase the weight and aid in digestion, constipation, rheumatism and nervousness, that there were no qualifications in these claims and the public was assured that if afflicted with the physical deficiencies mentioned, they would be cured by the use of Ironized Yeast, the Commission then cited the use of "before-and-after" pictures of persons described as having used the yeast product with beneficial results, and declared that they were not *bona fide* pictures of the same persons. The final disposition of the Commission's case has not yet (May 1934) been reported.

No 'patent medicine' could be successfully advertised without the use of testimonials, and anyone familiar with the "patent medicine" industry knows how easy it is to get testimonials. In 1930 it was brought out in this department of THE JOURNAL that the Ironized Yeast Company was circulating physicians. The letter that physicians received on the

stationary of the Ironized Yeast Company was headed in capital letters "A Gift Worth \$10 for You for Just a Little Information." Then the physician was asked to answer the following questions:

If you have ever prescribed yeast in your practice, for what disorders have you used it? What are your results in prescribing yeast for nervousness due to rundown condition for constipation? Have you ever taken it yourself?

Have you ever prescribed yeast plus iron (to be used together), and for what symptoms? What is your opinion of this combination for increasing the appetite, weight and as a general tonic?

The physician was to write his experience on his own stationery and send it to the Ironized Yeast Company. In return, the company promised to send him a bottle of perfume, or, as the Ironized Yeast letter more sonorously put it, "a luxurious flacon of exquisite French perfume—*Tout Paris de Gummel* regularly sold at \$10." To the layman the appeal is different. Purchasers of Ironized Yeast find in the circular that comes in the trade package an offer of a "Beautiful Picture For Framing—Free." The picture in question is of the Stone Mountain Memorial. In order to get this "free" picture, this is what the layman must do:

'Just write and tell us in your own words simply and naturally, like the friendly stories on the next page just what Ironized Yeast did for you. Tell us all the interesting details—how much weight you gained—what your friends think of your improvement—the activities you had to give up because of your poor health—any advancement either socially or in a business way your new health has brought you—how poor health, thinness or poor complexion once kept you back. These are the things we like to hear about. Then at the bottom tell us 'You may use this letter in any way you like to let others know what wonderful benefits Ironized Yeast will bring to them.'

Ironized Yeast comes in a bottle of fifty tablets costing \$1—that is, the tablets cost 2 cents apiece. The public is urged to take from eight to twelve tablets a day for from two to three months. At twelve tablets daily, a dollar package will last a little more than four days. The purchaser is urged to take Ironized Yeast for three months, which would cost \$21.60. The newspaper advertisements state that the company putting out the "patent medicine" guarantees results. Under the heading 'Results Guaranteed,' this paragraph appears:

'No matter how skinny and weak you may be this marvelous new Ironized Yeast should build you up in a few short weeks as it has thousands. If not delighted with the results of the very first package money back instantly.'

It takes careful reading of this alleged "guarantee" to show what it means. It will be noted that the company does not state that Ironized Yeast *will* "build you up in a few short weeks," but that it *should*. Furthermore, while the careless reader might get the impression that he could take Ironized Yeast for the three months that are recommended (at a cost of \$21.60) and at the end of that time, if he is not satisfied, could get his "money back instantly," this is not what the "guarantee" says. What it does say is that he must be dissatisfied with the results of the "very first package" (one dollar's worth). As one could hardly expect a transformation from emaciation to plumpness in the four days that a package lasts, the value of the "guarantee" is obvious.

According to the Ironized Yeast advertising, the product is "made from specially cultured *brewers ale yeast* imported from Europe"—claimed in earlier advertising to be from Bass' Ale brewery—which, it is alleged, "by a new process is concentrated 7 times." Further, this yeast "is then ironized with 3 kinds of strengthening iron." In some older advertising the president of the Ironized Yeast Company declared under oath that each Ironized Yeast tablet contained "the equivalent in vitamin strength of nine average yeast cakes a day." On a basis of twelve Ironized Yeast tablets a day, this would be equivalent to the vitamin value of 108 yeast cakes daily!

In the report of the Connecticut Agricultural Experiment Station issued in 1922, there was published an excellent piece of work by E M Bailey in collaboration with H C Cannon and H J Fisher on "The Potency of Some Commercial Vitamin Preparations as Compared With That of Dry Brewers' Yeast." Ironized Yeast was one of the preparations investigated. The various proprietary brands were not only analyzed chemically, but tested biologically. Young rats were placed on a diet lacking vitamin B. When the animal had shown a

can be accounted for by the most unusual finding of diffuse amyloid infiltration of the bone marrow. While it was not possible to demonstrate the presence of double refractile bodies or fat in the lymph nodes removed at biopsy, the presence of foam cells together with the clinical features of nephrosis and hypercholesterolemia warranted the diagnosis of lipid histiocytosis.

The present case serves to demonstrate the difficulty in the diagnosis of idiopathic amyloidosis, particularly since this condition presents a variety of clinical syndromes in which the disturbance in lipid metabolism may be prominent.

STAPHYLOCOCCUS TOXOID IN THE TREATMENT OF PUSTULAR DERMATOSES

To the Editor—The article by Kindel and Costello under this title in *THE JOURNAL*, April 21, is open to several criticisms.

The authors apparently set out to make a purely clinical assay of the efficacy of a particular commercial preparation of staphylococcus toxoid in the treatment of pustular dermatoses. Among a group of forty-two patients, including twenty-eight with acne vulgaris, eight with sycosis vulgaris and only six with furunculosis, a slight improvement was noted in eight while thirty-four were unimproved or worse after several injections of staphylococcus toxoid.

The authors concluded that these were unsatisfactory results and one does not cavil at their conclusion. But their further observation that "caution should be exercised in becoming over-enthusiastic about the value of staphylococcus toxoid until further reports confirm or deny our observations" seems entirely superfluous and unwarranted. Admittedly excessive enthusiasm of the type the authors probably had in mind exerts a baneful influence on the proper evaluation of any new biologic product. Since my paper in *THE JOURNAL* April 1, 1933 on the treatment of localized staphylococcal infections with staphylococcus toxoid is the only report of favorable results to which Drs Kindel and Costello directly refer, I beg leave to point out that a careful perusal of it will reveal no signs or symptoms of excessive enthusiasm on the part of its author. Moreover, it seems proper to state here that since the Connaught Laboratories began to manufacture staphylococcus toxoid for distribution to the medical profession in the Dominion of Canada, nearly twelve months ago, one has been far more concerned with endeavoring to dampen the excessive enthusiasm of certain clinicians who would use the product for almost any ailment than with challenging the skepticism of those who had not yet tested its efficacy in the treatment of localized staphylococcal infections.

But the results reported in my preliminary paper still stand and such favorable results are not 'denied' by any subsequent report of unfavorable results in which a different preparation is used. Though not "denying" the unfavorable results reported by Drs Kindel and Costello with their toxoid, further experience of the use of the Connaught Laboratories preparation of staphylococcus toxoid on a far greater number and variety of cases than were treated by these authors has indubitably confirmed my previous views as to its value in the treatment of localized staphylococcal infections. A paper summarizing my experience of the clinical use of this antigen for the past two years is in course of preparation.

To make my criticisms more particular the following points may be mentioned. First with regard to the patients selected for the investigation described in this paper not less than twenty-eight of the forty-two had acne vulgaris, a complex disease whose failure to respond to injections of staphylococcus

toxoid hardly constitutes a fair basis for disputing the efficacy of this product, when properly made, in the treatment of staphylococcal infections. Although in my hands remarkable degrees of improvement have often occurred from the use of toxoid in acne vulgaris when there has been bacteriologic evidence of superimposed infection with toxigenic staphylococci, there can be few dermatologists, and still fewer with a training in bacteriology who may have chanced to submit a comedone to anaerobic culture, who would maintain that the acne bacillus does not play a significant part in the etiology of this disease.

Second, with regard to the preparation of the toxoid, a single strain of staphylococcus was used in the manufacture of the original toxin, although there are many reasons for believing that several strains should be used and their toxins pooled. Again, the methods of preparation and assay of the toxin and its subsequent conversion into toxoid are of crucial importance. But such meager details as are given of their methods by these authors seem largely irrelevant, while no indication whatever is given of observations that may have been made regarding the antigenicity of the final product. Toxin filtrates were apparently assayed in terms of their necrotizing effect on the skin of rabbits, although the values so obtained are not given. But the three toxoids used in this study were accredited with "values of 200, 400 and 800 units per cubic centimeter respectively." Is it to be presumed from this statement that the toxoids retain a considerable degree of necrotizing effect on a rabbit's skin? If, as is more probable, the authors really meant that the original toxins showed strengths of 200, 400 and 800 rabbit dermonecrotic units per cubic centimeter before detoxication, one valid explanation of their failure to obtain favorable results at once presents itself. As was pointed out in my paper, the minimal dermonecrotic dose of toxins representative of those used in the preparation of the toxoids I used was 0.00014 cc. That is, the original toxins have often contained 70,000 rabbit dermonecrotic units per cubic centimeter. Furthermore, all my preparations of staphylococcus toxoid are carefully tested for antigenicity and innocuity, by assaying their power to provoke active antitoxic immunity in laboratory animals, before they are liberated for use in the treatment of human beings.

BRONCHIAL ASTHMA IN PREGNANCY

To the Editor—I read the paper entitled "Bronchial Asthma as a Complication of Pregnancy" by Dr Bradford Green (*THE JOURNAL*, February, 3, p 360) and also the communication in Correspondence (April 14, p 1248) from Dr R. H. Kampmeier, and would like to comment on Dr Kampmeier's letter. His contention that allergic manifestations disappear during pregnancy in contradiction to Dr Green's experience that there is aggravation of asthma during pregnancy, is also borne out by my experience of an interesting case.

A woman, aged 28, had had severe attacks of bronchial asthma for the past eight years. During pregnancy she was free of all symptoms of asthma and this absence of symptoms continued till three weeks post partum. When she was 30, I delivered her of her eighth child. All lived. The pregnancies occurred about one year apart to relieve her of her asthma. All the customary skin testing and injections of antigens and vaccines failed to prevent her asthmatic attacks when not pregnant.

I agree with Dr R. H. Kampmeier that a seasonal manifestation of allergy or bronchial asthma may be absent entirely if pregnancy includes the months of hay fever incidence. It must also be realized that though pregnancy, according to Dr Green, aggravates bronchial asthma, there is also ample evidence to prove that pregnancy relieves asthma and prevents attacks in some cases.

SAMUEL W. VERNICK, M.D., New York

THE MEDICAL PROFESSION AND PRISONS

To the Editor—There are 251 federal and state prisons in the United States, as well as 3,096 city and county prisons and jails. All the former institutions have one or more medical officers, and these institutions admitted last year more than 120,000 prisoners. Prisoners in all cases were committed to serve over a year, so that it is evident that there is a definite health problem in our prisons.

Of the 251 federal and state prisons there are at least 119 that have very inadequate medical service and show a gross neglect of the physical and mental care of their wards. These 119 institutions take care of about 30,000 individuals each year and turn them back into the population without consideration as to the individual's health. They pay no attention to the hazard to public health that these 30,000 individuals obviously create. Many of the other institutions are extremely lax in the medical care of their prisoners, and it is an unfortunate situation that in less than a dozen state prisons is adequate medical and surgical care being given to the inmates. Fortunately, the federal prisons are supplied full time physicians from the U S Public Health Service.

The widespread recognition which medicine has come to gain as an agency of social hygiene and social amelioration carries with it new opportunities and new responsibilities for the medical profession. It renders imperative the physician's emancipation from the individualistic tradition of aloofness which has gained control of the profession with the passing of the family doctor and of the innate personal relationships that could not survive under modern conditions of specialization. Unfortunately our prisons have enlisted to their service medical men who in many cases are castoffs of the profession—physicians who are failures and, consequently, obtainable at a beggar's fee. The administrators have been too prone to make the statement that even these derelicts of medicine are too good for the "gutter rats" confined to their cells. Scidom, if ever, does a warden or superintendent of a prison call on his institutional physician for professional care.

A detailed study of more than 2,000 prisoners in a large institution showed that only about 33 per cent of the prisoners were really normal individuals intellectually and emotionally, 24 per cent were definitely feeble-minded, and 75 per cent were mentally so unbalanced as to be diagnosed psychotic or potentially psychotic, 82 per cent of the inmates suffered from poor eyesight, and 1 per cent more had some definite eye infection, 19 per cent had obstruction in the nose, while 0.9 per cent had ear trouble. At least 6 per cent suffered from correctable defects, such as hernia and flatfoot. Slightly over 5 per cent showed definite indications of tuberculosis and at least 0.2 per cent had active signs of tuberculosis, 12.5 per cent had active gonorrhea and 85 per cent syphilis in some form, while 50 per cent had poor teeth, 25 per cent heart trouble, and at least 55 per cent had tonsils or adenoids that needed to be removed. At least 3 per cent were undernourished when they came into the institution, and a majority suffered from disorders of the digestive system.

It is a tragic commentary on the American system that our prisons are filled with poor people, those who in a majority of cases cannot afford to employ legal aid and who also probably did not employ medical aid previous to their commitment. Most prisoners come from wholly inadequate homes and society seems to hold to the belief that the home can do no wrong and that antisocial behavior is the individual's responsibility. However, there is no doubt that, once the prisoner has been deprived of his legal rights as a citizen and become a ward of the state, it is the state's responsibility to furnish that individual the highest type of medical and surgical care. And certainly since far the majority of these prisoners will again be released into the community, they should be given the necessary treatment

while under confinement to refit them into society as normal individuals, if possible, without handicaps.

The medical profession should take an interest in this matter and lend its support to raising the standard of the profession in these important institutions. Much can be done by the profession to remedy this situation. If the standard of medical care in our prisons could be raised to the standard it should be, undoubtedly it would act as a prevention of crime. If the prisoners were released better than when they were committed, there would not be the resentment against society for depriving them of their liberty. But it is extremely unfortunate that, in most cases, prisoners today stand a chance of release from prison in a more deplorable state than when they were committed to incarceration.

Section, American Prison Association

Queries and Minor Notes

ANONYMOUS COMMUNICATIONS and queries on postal cards will not be noticed. Every letter must contain the writer's name and address, but these will be omitted on request.

BARBERS' ITCH

To the Editor—What would you suggest for barbers' itch? Please do not publish my name.
M. D. Oklahoma

ANSWER—Barbers' itch is a popular name for any infectious disease of the skin of the bearded region. Impetigo contagiosa, including sycosis vulgaris, the form named after Bockhardt, caused by bacteria, the tinea form of sycosis, and the rare disease called lupoid sycosis are most properly designated barbers' itch, but syphilis, lupus vulgaris, lupus erythematosus, actinomycosis or blastomycosis, occurring in the bearded area, might be so named by the public. Only the former group will be considered in this discussion.

Impetigo contagiosa is characterized by initial vesicles arising from apparently normal skin, the vesicles quickly becoming pustular and bursting, leaving an erosion, which is soon covered by a thin crust, typically covering the whole erosion so that it seems stuck on with edges slightly upturned. Not seldom the pustule does not burst but the contents are absorbed and the roof sinks down and becomes part of the crust. When the crust falls, a red macule is left, which slowly fades to the normal skin color. There is no scar. In the meantime other lesions have appeared wherever the infection has been carried by the fingers or other means, often by the razor or shaving brush, in the bearded region. Sometimes circinate figures are formed by peripheral extension of the bulla with central healing. In other cases the bullae may become quite large.

Bockhardt's impetigo is a very superficial folliculitis, the lesions small. It is more often confined to the bearded region than the common form of impetigo, which tends to involve other parts of the face, scalp, hands and other parts of the body.

Both forms of impetigo are superficial processes, usually yielding readily to simple antiseptics, as ointments of ammoniated mercury in a strength of from 2 to 10 per cent. In stubborn cases, painting the erosion with a solution of silver nitrate, from 2 to 5 per cent, may hasten cure. The ointment being used on the skin between. In those sensitive to the mercurial gentian violet, in 5 per cent aqueous solution, may be painted on once a day. The secret of success in treatment is to watch for new lesions to treat them promptly, and to warn the patient of the danger of spreading the infection by means of the fingers, towels or razor. Shaving should be omitted during the course of disease, the beard being clipped instead. All cleansing operation should be first carried out on the noninfected part of the face, the infected part treated last, and the hands, towels and scissors carefully cleansed afterward.

Sycosis vulgaris infection of the hair follicles by pus organisms, is often confused with Bockhardt's impetigo, but sycosis is much deeper, causes swelling of the skin and loosening of the hairs and does not heal on simple treatment though it may clear up temporarily. Any part of the beard may be involved but the upper lip is a favorite site infected by nasal

discharges. Frequently this is the only part infected at first. The characteristic lesion is the follicular pustule on a base of swollen, reddened skin. From day to day the infection varies in severity, at times almost clearing up, leaving only a few papules to mark the site, then suddenly becoming severe again.

In contrast, tinea sycosis is more apt to involve the neck below the angle of the jaw and seldom is seen on the upper lip only, though a few such cases are on record. Instead of the ill defined patches of erythema studded by pustules, ringworm sycosis usually forms sharply defined patches round oval or polycyclic sometimes becoming circinate by central clearing, but more often forming patches composed of granulomatous tumors from which pus oozes in many places corresponding to the kerion Celsi seen in the scalps of children with ringworm infection. These violently inflamed patches are due to infection with large spored ringworm, often *Trichophyton gypsum* to which the skin reacts vigorously and establishes a considerable immunity, killing a large part of the organisms. For diagnostic purposes the hairs from the edge of the patch should be examined, for those in the center frequently do not show organisms. Because of the violent reaction these cases yield to treatment more readily than bacterial sycosis. Discovery of the organisms about the root of the hair after soaking the specimen in 10 per cent potassium hydroxide for from a few hours to three days is usually possible. The tumor-like character of the infected areas and the unilateral or at least asymmetrical distribution are important differences from the bacterial form of sycosis. Ringworm of the beard is comparatively rare.

Lupoid sycosis is a rare disease in which large circinate lesions, sometimes occupying the whole cheek, are seen. The center is formed in part at least by atrophic or deep scars, the active border only a few millimeters in width, formed of papules, vesicles and pustules. It is highly resistant to treatment.

Treatment is much the same for all forms of sycosis. Wet dressing of solution of aluminum acetate 1 part to 15 parts of water, or saturated solution of boric acid or surgical solution of chlorinated soda are indicated for the pustular conditions, these being alternated with ointments of ammoniated mercury, sulphur or resorcinol for the bacterial disease, salicylic and benzoic acid for the tinea infection. Tincture of iodine is one of the most useful applications but it should be weakened to 50 per cent strength with alcohol for most cases and should not be alternated with mercurials for fear of producing dermatitis venenata. In some cases this may be done intentionally on a small area, the violent inflammation aiding in recovery.

Shaving must be prohibited, the beard being clipped instead. All infected hairs must be epilated each day. In some cases such treatment, if kept up for several months after apparent cure, may be successful. Too often, however, the condition recurs as soon as the treatment stops.

Mild treatment with x-rays in divided dosage one-fourth erythema dose once a week, may clear up sycosis vulgaris. With it only the milder forms of antiseptic treatment should be used, as 5 per cent ointment of ammoniated mercury alternating with cool wet dressings of solution of aluminum acetate. If twelve weeks of such treatment fails to cure, more vigorous measures must be taken, complete epilation of the affected parts. This may be accomplished by radium or x-rays. Thallium acetate, even in half dose as suggested by some, is too dangerous to be given to adults. In cases in which x-rays in divided dose are given, a month or more without treatment should be insisted on before attempting epilation. The patient must understand that there is some danger of later atrophy of the skin, and his signature to a release may be of value.

Two methods are recommended by G. C. Andrews (Diseases of the Skin, Philadelphia, W. B. Saunders Company 1930, p. 516), the divided dose method, one-fourth erythema dose through 3 mm. of aluminum every third day for four doses, then a fifth irradiation of the same strength a week after the fourth. The massive dose, seven eighths erythema dose in one application, through 3 mm. of aluminum may be preferred. The hair comes out in about three weeks. Remaining hairs must be epilated mechanically and then the use of antiseptics begun for the epilation is only preparation for the real treatment intended to protect the new hairs from becoming infected.

Tincture of iodine at first diluted to half strength later in full strength, may be applied daily until the skin becomes dry with a tendency to fissure. Then an ointment is used. Whitfield ointment, 2 per cent salicylic acid and 4 per cent benzoic acid in ointment of rose water, for the tinea sycosis or sulphur and resorcinol of each 3 per cent in the same base for the bacterial form of the disease. Some such application must be kept up until the new hair is well grown. If small focal recurrences show themselves mechanical epilation and stronger antiseptics must be used. Treatment should be kept up for at

least a month after all signs of the disease have disappeared. Then the patient should report regularly for several months for inspection.

No possible means of increasing the good health and resistance of the patient should be neglected. A generous well chosen diet, containing plenty of vitamins, regular exercise outdoors, sunlight or ultraviolet radiation regular hours of sleep and an effort to get rid of any focal infection other than that in the beard are essential. Even the most thorough and painstaking treatment often fails to cure these cases.

EFEMIST (HART) AND EFEDRON (HART)

To the Editor—Are there any therapeutic advantages of Efemist and Efedron (Hart) over similar nonproprietary preparations? Recent circulars of the Hart Drug Corporation of Miami, Fla. claim verification editorially, in recent issues of THE JOURNAL of this attitude.

M. D. Palo Alto California

ANSWER—In Queries and Minor Notes in THE JOURNAL, Feb. 8, 1930, page 430, the formula for Efedron was stated as:

Ephedrine hydrochloride	Gr 1
Chlorbutanol	Gr 2½
Sodium chloride	Gr 2½
Menthol	Gr 3
Phenol	Gr 2
Oil of cinnamon	Gr 0.08
Jelly base	q s ad drachms 5

It was stated at that time that, although liberal samples were being distributed among the profession, nevertheless the carton was seemingly, addressed to the public as well.

Efemist, according to the advertising of the manufacturer, contains 1 per cent ephedrine hydrochloride and ¾ per cent chlorbutanol, in addition to undeclared amounts of menthol, eucalyptol, phenol and sodium chloride in a "special water and tissue fluid soluble base."

Of course, neither Efedron or Efemist has been accepted by the Council on Pharmacy and Chemistry, nor has the manufacturer requested Council consideration of the products.

Under date of March 2, 1934, a circular letter to the profession from the Hart Drug Corporation stated as follows:

'Would you knowingly care to prescribe any preparation that was injurious to the physiological function of the tissues to which it is to be applied? Undoubtedly not! Yet in the selection of preparations intended for localized nasal mucous membrane application it is amazing how frequently certain fundamentals in this respect are being overlooked.

'For a number of years we have been consistently endeavoring to point out to physicians why water soluble preparations are for superior to oily preparations in this form of therapy. In this connection it may be interesting to note that editorially, THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION Vol 101 No 19 directs attention to the fact that on oily base in ephedrine containing preparations is deleterious to the cilia of the nasal mucosa.

Also, in Vol 102 No 1, of the same publication while the harmlessness of the long continued use of ephedrine nose drops is shown attention to the dangers of oil containing solutions are pointed out.

EFEMIST (Hart) contains not a single drop of oil to interfere with ciliary activity. Indeed in this preparation the vehicle holding the active ingredients is both water and tissue fluid soluble thus making ephedrine available to the tissues rapidly and in maximal quantities.

Therapeutic success largely depends upon the details of the therapeutic fine points and while there exist many ephedrine containing solutions at your disposal we believe that NONE have been evolved which take into consideration as many points of therapeutic nicety as EFEMIST.

The reference to THE JOURNAL (italics ours) represents either misunderstanding or deliberate misinterpretation. The sources referred to appear among Queries and Minor Notes, they were not editorials. In the first note (THE JOURNAL, Nov. 4, 1933, p. 1503) it was stated:

It has been stated by some research workers that the oil has a deleterious effect on the cilia but bad results have not been observed from the use of liquid petrolatum to which a small amount of ephedrine has been added.

In the second reference (THE JOURNAL, Jan. 6, 1934 p. 67) it is reported, in part that:

One must guard against the use of too much ephedrine at a time with a resultant swallowing of the drug with its constitutional reactions. In very young children nose drops of oily character have been known to enter the lung producing undesirable reactions.

One fact is obvious that oily solutions of ephedrine when used properly are not injurious to the nasal mucous membrane. That is the fact which it was the intention of each article to point out. No comparison was made of watery with oily solutions and it was certainly furthest from all intent in either Query and Minor Note even to suggest that the unacceptable proprietary mixtures Efedron and Efemist, are to be commended or that they are superior to oily solutions of ephedrine.

STENCIL INK POISONING

To the Editor—I have a patient who is suffering with a peculiar edematous condition. He is inclined to think that his illness is due to a chronic poisoning with stencil ink. Could this be possible? If so, where could I find literature on stencil ink poisoning?

EDWARD TRIFFEL M.D. O'Fallon, Ill

ANSWER—From the description it is difficult to tell whether a dermatitis is present or some other type of generalized edema. The majority of poisonings described as due to ink have been forms of dermatitis or eczema. Several types of materials may be responsible for the inflammation. The ordinary inks may cause irritation either because of their irritating nature or because of the dryness of particular skins. There have been reported also instances of rotogravure ink dermatitis. In other instances it has been found that the cleaning materials used to remove ink stains have been the causative agents for the dermatitis. A fairly thorough search of the literature does not disclose a separation of stencil ink dermatitis from other forms of irritation due to ink. The following references may be found useful:

POLYCYSTIC KIDNEYS—KETOGENIC DIET IN UROLOGY

To the Editor—1 Please give the latest accepted theory on the causation of polycystic kidneys and the percentage of occurrence with prognosis and treatment. I would appreciate an elaboration in detail on treatment. It has been my opinion that once these cases were diagnosed the patient should be treated by an internist rather than by a urologist. Am I right or wrong? 2 Would you mention the value of the ketogenic diet as applied to urology? Please omit name.

M.D. District of Columbia

ANSWER—1 Polycystic kidneys are recognized clinically in an incidence of only about 1 in 3,500 patients, but are found at postmortem examination in about 1 in 1,000 persons. The cystic condition of the kidneys may be associated with cystic disease of the liver, but the cysts of the liver are usually confined to limited portions and seldom produce symptoms of hepatic disease. Polycystic kidneys are always bilateral, although, for a time at least, one kidney may be much smaller than the other and its condition may escape recognition or palpation. The condition must be distinguished pathologically from solitary cyst of the kidney, in which, although the cysts occasionally are multiple, they seldom are so numerous or of such a character that the condition of solitary cyst can be confused with that of polycystic kidney.

The cause of polycystic kidneys is not known, but they are believed to be due to a developmental defect and to be related to inadequate fusion of constituent parts of the renal units. A tendency for the condition to be hereditary has been noted by many observers and constitutes one of the chief proofs of its congenital nature. It has been suggested that it would be logical to consider limitation of progeny by the afflicted, in view of the pronounced hereditary tendency, but as patients are generally beyond the usual child-bearing age when the diagnosis is made, the suggestion seems more academic than practical.

The symptoms of the condition are usually not noted until the patient is between 40 and 50 years of age. A dull pain over either kidney may be the only early symptom. Frequency and dysuria may be noted. In about a third of cases, gross hematuria may occur at intervals. A sudden hemorrhage into a large cyst or a ureteral obstruction due to blood clots may produce acute renal pain simulating colic. Symptoms and signs of renal insufficiency eventually ensue, and these include hypertension in the majority of cases, contrary to the opinion of some. Death may result from uremia or vascular accidents.

In polycystic renal disease when hematuria and an abdominal tumor, mistakenly considered to be unilateral, are noted an erroneous diagnosis of renal neoplasm may be made and operation performed, leading to serious consequences. Intravenous urography may be necessary to complete the diagnosis of polycystic kidneys, for urographic signs are generally characteristic. Bilateral simultaneous pyelography in this condition may be dangerous.

The prognosis depends largely on the degree of renal insufficiency resulting from the varying rates of formation of cysts and consequent excretory embarrassment. The prognosis is good as long as renal function remains normal or nearly so.

Even with moderate renal insufficiency, patients may live comfortably for ten or fifteen years, and concentrations of urea of more than 100 mg per hundred cubic centimeters of blood may be remarkably well borne for several years. In fact expectancy of life in this condition averages about fifty years and patients occasionally have lived to be more than 60 years of age if they have exerted reasonable care. Data on 193 cases have been recently reported by Braasch and Schacht (*Surg, Gynec & Obst* 57: 467 [Oct] 1933). Of forty-two patients known to be alive, twenty-five were living at least ten years and nine more than twenty years after the onset of symptoms. One patient lived twenty-three years, another, thirty-six years after the first symptoms. Of seventy-four patients reported dead, twenty-two died within two years and eleven within four years of the first symptoms.

Medical treatment alone is generally indicated, although surgical treatment may be required when severe secondary infection involves one kidney, or when very large cysts cause considerable discomfort, producing in some cases mechanical obstruction to excretion of urine. Surgical evacuation and destruction of large or hemorrhagic cysts may then give relief. It must always be remembered that the condition is bilateral. Medical care is concerned with the usual measures for chronic renal insufficiency and is directed toward restrictions in diet and in exercise, supervision of hours of rest, and prevention of intercurrent infections. All strenuous exercises and labor should be avoided, but less vigorous types of physical recreation, such as short walks, are permissible. The patient should have ten hours' rest in bed at night and if at all possible a rest at noon of one hour. If renal function is still normal, rigid dietary restrictions are probably not indicated. Such measures are saved for future requirements. If the value for urea is more than 40 mg per hundred cubic centimeters of blood, the daily diet should contain only about 40 to 60 gm of protein. Carbohydrates may be taken as they are necessary for adequate caloric intake. Restrictions in intake of salt are necessary if edema impends, otherwise just enough salt to season food palatably should be allowed. A daily intake of fluid of about 2,000 cc should be insured unless significant edema appears, when moderate restriction of fluid may be necessary, edema, however, rarely occurs. A daily warm bath, mild laxatives or warm enemas may increase adventitious elimination of metabolites. Ample clothing, prevention of undue exposure to cold, and when possible, a sojourn in a warm, dry climate are desirable. If the patient is in middle age and little or no renal insufficiency is present any chronic source of infection should be removed, but the time for its removal must be carefully chosen.

2 The use of the ketogenic diet in the treatment of bacilluria, if there are no anomalies of the urinary tract, is steadily gaining favor. Even when anomalies are present, Helmholtz has noted successful results, but Rennie's results (*Arch Dis Childhood* 8: 47 [Feb] 1933) in four cases of pyuria associated with abnormalities of the urinary tract were disappointing. In uncomplicated cases Rennie reported satisfactory sterilization of the urinary tract. The rational method of treatment and results of this diet have recently been briefly reviewed in *Queries and Minor Notes* (*THE JOURNAL*, Oct 28, 1933, p. 1413).

It must be stated that the ketogenic dietary treatment of bacilluria of the *Escherichia* type thus far has been more successful than that of the aerogenes type of infection. Successful treatment in any case requires hospitalization under the care of a dietitian and with the cooperation of a laboratory expert as Wilson (*Post-Grad M J* 9: 96 [March] 1933) has emphasized. The correspondent also could well refer to Crance (*Urol & Cutan Rev* 37: 528 [Aug] 1933).

DERMATITIS FROM CRUDE OIL

To the Editor—I would like information concerning dermatitis (industrial) from contact with crude oil or crude petroleum.

JOSEPH M. ADAMS M.D. New Orleans

ANSWER—Crude mineral oil like other oils, causes an acne-like eruption on the skin coming into constant contact with it. The bare forearms and the covered parts in contact with oil-soaked clothing are most often affected. First are seen comedones, plugs of thick oil or paraffin, which fill the follicle mouths and collect dirt. They cause an inflammation about the follicle with pus formation in nature's effort to get rid of them. A deep pustule results which often heals with a scar. Except for the distribution, which affects the parts exposed to oil instead of the face, neck, upper part of the chest and upper part of the back, and for the accompanying hyperkeratosis, this eruption is like that of acne vulgaris. Later the skin becomes thickened and pigmented, the keratotic papules persist and a certain proportion of them become epitheliomas.

Of English workmen of long service in work that exposes them to constant contact with oil and who are over 40 years of age 01 per cent develop epithelioma each year. Fifty per cent of them have some skin trouble. Even though they quit the oily job, they may develop epithelioma years afterward. Mule spinners—men whose work consists of reaching over a spinning machine while it is in motion, in order to mend broken threads, with consequent drenching of their clothes with the lubricating oil—are frequent sufferers from epithelioma of the scrotum. Sequeira reports the occurrence of epithelioma in thirteen such workers from one to fourteen years after quitting the job (Cancer and Other Diseases of the Skin Caused by Mineral Oils, *Kenya & East African M J* 6 18 [April] 1929).

Oils from Borneo, Assam, Egypt, Burma and Badapur are most irritating and most likely to cause dermatitis and epithelioma. Those from Galicia, Russia, California and Persia are less irritating. Shale oil is also classed among the irritating oils. Purification with sulphuric acid renders the oil harmless, as does oxidation or reduction. Oil tumors are reportable in Great Britain. During 1926 there were 187 such cases reported, of which 47 were fatal. French law allows compensation for such injuries.

Twort and Fulton found that most American oils are only slightly carcinogenic. Experiments on the Nature of the Carcinogenic Agents in Mineral Oils, *J Path & Bact* 32 149 (1929). The active carcinogenic agent is concentrated in extracts made with methyl sulphate or methyl sulphate and trinitrophenol and this process is useful in testing oils intended for industrial use.

Because of the fear that medicinal mineral oils might also be harmful, F C Wood (The Noncarcinogenic Nature of Purified Mineral Oils, *THE JOURNAL*, May 24 1930, p 1641) tried them out on the skin of albino mice, known to be particularly susceptible. Mineral oil for therapeutic use was found harmless, whether painted on the skin or administered internally. Heavy lubricating oil, painted on the skin three times a week for one year, caused a few "warts" (keratotic papules), while painting the skin in the same way for the same length of time with tar caused many keratoses and a considerable percentage of epitheliomas.

Treatment of the dermatitis and prevention of the epitheliomas are both accomplished by cleanliness, thorough scrubbing of the skin with soap and hot water each day after quitting work, and protection from oil-soaked clothing. An oil-proof outer garment should be provided and the workmen inspected carefully, with particular attention to the groins and scrotum, every month or so. The tumors when present must be widely excised or thoroughly treated with x-rays or radium, for they are squamous cell epitheliomas, more malignant than the usual basal cell type.

POLYCYTHEMIA

To the Editor—A woman aged 64 the mother of six children until the last three or four years strong and industrious now has lack of strength and wearies easily. I sent her to a hospital recently and the red blood cells are reported as numbering 8 000 000 together with a slight trace of albumin and indican. The lungs are clear. There is slight cardiac enlargement. The complaints are weakness and anorexia. Is not phenylhydrazine hydrochloride recommended in cases of this nature? Where can it be obtained and what is the dosage? I have her on a fruit juice diet largely. She has always been temperate except perhaps as to work and eating. She weighs 140 pounds (63.5 Kg.) What is supposed to be the etiology of polycythemia? Please omit name.

M D Texas

ANSWER—Before any therapeutic measures are employed, it should be determined that polycythemia rubra vera is the condition responsible for the patient's complaints. This may be accomplished by careful confirmatory blood studies, the presence of an enlarged spleen, a peculiar red cyanosis, a definite although slight elevation in the basal metabolic rate, and the absence of any other condition that might give rise to a secondary polycythemia (especially chronic cardiac and pulmonary disease). If polycythemia vera is present at least two conservative forms of treatment may be given: a trial repeated venesection and irradiation of the long bones. It is generally agreed however, that the results following the use of phenylhydrazine are more satisfactory than with the two previously mentioned forms of treatment despite the fact that the drug may cause undesirable toxic effects.

Phenylhydrazine hydrochloride should be given in capsules by mouth in doses of from 0.1 Gm (1½ grains) to 0.2 Gm (3 grains). A patient receiving such treatment should be under close observation and the result of the therapy gaged by frequent blood examinations. If there is a fall in the red blood cell count and hemoglobin to approximately normal after from 1 Gm (15 grains) to 3 Gm (45 grains) has been taken,

the therapy should be discontinued to observe whether a cumulative effect occurs. An increasing number of immature red blood cells or an increase in the number of white blood cells is an indication to discontinue the treatment temporarily. If there is no cumulative effect, and the red blood cell count remains significantly elevated, another gram (15 grains) of the drug may be given in daily doses of from 0.1 to 0.2 Gm. After the blood has reached normal limits, smaller doses should be given to maintain it at this level. The dosage required varies with each individual patient but usually averages between 0.06 Gm (1 grain) and 0.3 Gm (5 grains) weekly. As this drug is a protoplasmic poison, it should be given only to patients who can be observed at frequent intervals and to those in whom the therapy can be guided by frequent and careful blood studies. More recently Stone, Harris and Bodansky (*The Treatment of Polycythemia Vera*, *THE JOURNAL*, Aug 12, 1933, p 495) have advocated the use of acetylphenylhydrazine, as they consider that it is therapeutically effective and is less toxic than phenylhydrazine hydrochloride. It is impossible to appraise its value definitely until a larger group of patients has been treated, although it appears to have considerable promise.

The etiology of polycythemia is unknown but the disease is considered by some to be due to a neoplastic change in the bone marrow which in some respects resembles leukemia. Others consider that it may be due to some disturbance of hormone control of bone marrow activity.

Phenylhydrazine preparations may be obtained through one's druggist from any large manufacturing firm.

INHALATION OF WATERMELON SEED

To the Editor—In August 1933 I was called to see a year old child with a watermelon seed in its lung. The seed had been inhaled a few minutes previous to my call and the child was exhibiting a noisy and difficult respiration and a hoarse cough. Cyanosis was not present. The child was hospitalized and roentgenograms were taken of the chest, but these failed to show the location of the seed or evidence of air trapping. Because the foreign body could not be located bronchoscopy seemed contraindicated and I waited in the hope that the seed might be coughed up. This happened three weeks later, and a swollen somewhat eroded seed was coughed up. During its stay in the hospital the baby had a low grade temperature and continued to cough and wheeze. After the seed was coughed up the temperature returned to normal but the coughing and wheezing continued and is still present. The wheezing seems to originate in the larynx or upper part of the trachea and with the exception of the transmitted wheezing sounds the lungs seem clear. The baby has no fever at present and with the exception of the labored breathing seems to be in good health. I wish you would outline any further treatment you feel might help the cough and wheezing to disappear and the child's breathing return to normal. Please omit name.

M D Wisconsin

ANSWER—The history is quite the usual one for cases of inspired watermelon seed. The wheezing with absence of roentgenographic signs of emphysema or atelectasis is diagnostic of foreign body in the trachea. In this position, one lung is not affected any more than the other, consequently there is no difference of aeration as between the two lungs by either physical or roentgen signs. The persistence of the wheeze after the spontaneous expulsion of the foreign body indicates some narrowing of the airway by another foreign body (exogenous or endogenous) or pathologic condition. Only a diagnostic bronchoscopy would determine which of these possibilities is present. Treatment would depend on conditions found at bronchoscopy.

SENSITIVITY TO MERCURY

To the Editor—A man aged 37, when first seen was suffering from an acute nonpurulent conjunctivitis. Topical applications of 2 per cent zinc sulphate were made to the lids; they were washed with physiologic solution of sodium chloride and an ointment containing the following formula was given to instill between the eyelids at night: yellow mercuric oxide 10 parts, solution of epinephrine hydrochloride 40 pts, zinc sulphate, 1 part, horic acid solution 150 parts, wool fat 190 parts, petrolatum 609 parts. When seen three days later the eyelids were markedly swollen and red and the patient complained of the severe itching. This subsided within three days when he no longer used the ointment. He tells me that he lost a finger some years back and his hand was soaked in a blue solution (mercuric chloride solution, I thought). His hand swelled up to twice its normal size. Is it logical to assume that this man reacted to the mercury in the ointment? He has a + Wassermann and 3+ Kahn test. Will antisyphilitic treatment without mercury be adequate? I have never seen such a reaction in the eyes or recall reading about it. Is it rare? Please omit name.

M D Ohio

ANSWER—It is possible that the patient developed a sensitivity to mercury (almost an allergic phenomenon). Antisyphilitic treatment without mercury, a bismuth compound being substituted, would be adequate. Such reactions are uncommon.

CAVITIES IN DECIDUOUS TEETH

To the Editor—What is the consensus among the best dentists about filling cavities in deciduous teeth? If this is not the accepted procedure, what is? Please omit name and address

M D North Carolina

ANSWER—The constantly increasing demand for education on the part both of the public and of the dental profession has brought the problem of prevention of decay and all the ills that follow in its wake to a point at which the leaders in education agree that the whole solution centers on its early prevention.

Evidence is at hand that school children develop more rapidly both mentally and physically if their mouths and teeth are regularly under the care of the dentist.

The deciduous teeth should be retained until the permanent ones are ready to erupt, their roots being absorbed to accommodate them. If the deciduous teeth are taken out or are lost by decay before the permanent ones are ready to take their places, the arch becomes too narrow and irregularity follows. This can be corrected only by the orthodontist. The deciduous teeth should be filled as soon as decay appears. They should be kept clean by the systematic use of the toothbrush. If cavities in deciduous teeth are not filled, the child loses the use of the teeth, their pulps die, and abscess and destruction of the jaw bone follow. Adentitis results, even tuberculous germs may enter glands through cavities in the teeth. Digestion is impaired, the child suffers pain, and impairment of the health and of development follows. There is no sane argument for allowing deciduous teeth to decay. Cavities should be filled as soon as they occur. Children should visit their dentist at least every six months and oftener if necessary.

The consensus among the best dentists is that all deciduous teeth, when carious, should be filled and retained until the permanent ones are ready to take their places.

SODIUM MORRHUATE IN INJECTION TREATMENT OF HEMORRHOIDS

To the Editor—Kindly advise whether sodium morrhuate is commonly used in the injection treatment of hemorrhoids and what advantages if any, it has over quinine and urea hydrochloride. Please omit name.

M D New York

ANSWER—Sodium morrhuate may be used in the injection treatment of hemorrhoids but is not considered as efficient as quinine and urea hydrochloride or the phenol and oil solution.

SIMULTANEOUS IMMUNIZATIONS

To the Editor—In Queries and Minor Notes in THE JOURNAL April 14 page 1251 was an inquiry as to simultaneous immunizations. In the answer the statement is made that it is not known for instance whether successful vaccination against smallpox would interfere in any way with the immune reactions against scarlet fever toxin diphtheria toxoid or pertussis vaccine. In the State Public School at Owatonna Minn. where children from a few days old to the age of 16 are received from all parts of the state cared for and later placed in homes if possible, it is our routine to vaccinate against smallpox and give toxoid or other vaccines the same day. In the last ten years we have followed this method in more than 2,000 children with no complications and have the usual number of successful vaccinations and the usual number of negative Schick or other tests when given at the proper time following.

A B STEWART M D Owatonna Minn

To the Editor—A query from Dr. Stern of Chicago in Queries and Minor Notes (THE JOURNAL April 14 p 1251) relative to simultaneous immunizations prompts me to report my experience.

In 1932 350 school children were given simultaneous immunizing injections of diphtheria toxoid and typhoid vaccines each child receiving two doses of diphtheria toxoid and being given a dose of typhoid vaccine with the toxoids.

I made Schick tests on these children in March 1934 and found exactly five Schick positive children in the entire group. The same thing occurred in Miami Ariz. where 180 children were given simultaneous immunizations against typhoid and diphtheria also in 1932. In this group there were three Schick positive children in February 1934.

Children in both groups gave histories of considerable reaction during the immunizing period and while I would not suggest the undertaking of simultaneous inoculations owing to such reactions occurring in these groups yet I quote the low percentage of Schick positive children resulting when concurrent immunizations were given.

ALSON B INGELS M D Globe Ariz

Director Gila County Health Unit

EDEMA OF THE EYELIDS

To the Editor—In Queries and Minor Notes in THE JOURNAL April 14 page 1249 M D Massachusetts inquires about edema of the eyelids. Your reply is complete with the exception of one condition not mentioned though it is the cause of most puffy but nonedematous eyelids. This condition is an accumulation of fat in the loose periorbital tissue. Resection of an ellipse of skin will eliminate redundancy but will not correct puffiness; this can be accomplished only by resection of infiltrated fat.

Book Notices

Blindness and the Blind in the United States. By Harry Best. Cloth Price \$6.50. Pp 714. New York: The Macmillan Company, 1934.

The seven parts of this book deal, respectively, with blindness and possibilities for its prevention; general condition of the blind; provision for education of blind children; intellectual provision for the adult blind; material provision for the blind; organization, interested in the blind; and conclusions with respect to work for the blind. It is a comprehensive and painstaking compendium of information gathered from so many sources that it would seem scarcely possible that any have been overlooked. It is full of statistical studies made with admirable restraint in interpretation of figures. It is documented with exceptional completeness. Without shrinking from facts or in any way minimizing the problem, it presents an encouraging picture of possibilities for the alleviation of the condition of the blind in the United States. It emphasizes that the present movement in medical research and social investigation is one of prophylaxis. It emphasizes the preventable nature of such common causes of blindness as trachoma, ophthalmia neonatorum and accidental injuries. Except for hereditary blindness, which is characterized as a small part of the total problem though sufficiently conspicuous and tragic in individual families the outlook is favorable. The keynote of the investigation is to be found in these sentences in the introduction: "Concern in the blind that is based upon their actual position in society and the treatment which they have received from it, purely as a matter of scientific inquiry—though in no wise removed from a profound human love, and indeed wrapped about therewith—has been of secondary moment. In other words an examination of the blind and of their estate from the point of view of the social economist—the presentation of something of what has come to be known as a social survey—respecting them—has as a comprehensive study been wanting. The object of the present work is to consider the

blind as respects the United States, with this latter conception in mind." The book is not one for reading in idle moments. It is a condensed work of reference which ought to be of interest to students, sociologists, legislators, educators and physicians.

Alcohol: Its Effects on Man. By Huxley Emerson, M.D. Professor of Public Health Practice, Columbia University. Cloth Price \$1. Pp 114. New York & London: D. Appleton Century Company, Inc. 1934.

This book is no doubt an outgrowth of a larger work edited by Dr. Emerson and published during the past year. The purpose of the little volume is to provide school teachers and students with the facts regarding the actions and effects of alcohol on man as they are now known to the medical sciences.

Dr. Emerson lists fifteen well established facts regarding alcohol in relation to illness with which no doubt the vast majority of physicians will agree:

1. Alcohol is a narcotic which, by depressing the higher centers removes inhibitions.
2. Outside of the nervous system and the digestive tract, alcohol used as a beverage has little demonstrable effect.
3. It is a food utilizable as a source of energy and a sparer of protein but it is such only to a very limited extent.
4. It is improbable that the quality of human stock has been at all injured or adversely modified by the long use of alcohol, although the effects on the individual are often devastating.
5. The therapeutic usefulness and value of alcohol are slight.
6. It may be a comfort and a psychological aid to the aged.
7. It does not increase and it sometimes decreases the body's resistance to infection.
8. By releasing inhibitions it makes for social ease and pleasure and herein lies one of its great dangers.
9. Its effects are best studied by changes of conduct.
10. It impairs reason, will, self control, judgment, physical skill and endurance.
11. It may produce situations from which crime and social lapses result.
12. It is a frequent destroyer of health, happiness and mental stability.
13. Its use commonly lowers longevity and increases mortality.
14. It is used primarily for its psychological effect as a means of escape from unpleasant reality.
15. It constitutes an important community health problem.

He correctly states the chief problem confronting the world today in relation to the use of alcohol as the necessity for each individual to "decide for himself whether his own personal satisfaction in the escape from physical and mental unpleasantnesses, which alcohol in moderation may bring him at the cost of appreciable hazards to his own health and to his livelihood, warrants his exposing others, less capable of moderation, to opportunities of becoming users of alcohol to their and society's damage and cost."

Enfance et hérédité. Par A. Lesage, médecin honoraire des hôpitaux. Paper Price 20 francs. Pp 104 with illustrations. Paris: Masson & Co. 1933.

This is a spontaneous outpouring of observations in two parts and nine chapters to demonstrate that "the living are governed by the dead." The first portion considers in five chapters the subject of heredity in general. The author points out the limitations of tubularly viewing bacteriology and chemistry. He insists that the view must be broader to include the forebears or source of the child who is sick. In other words it is important to know that a given child has pneumonia but equally important to know what kind of child it is who has the pneumonia. The second chapter of three paragraphs and nine lines concisely states that syphilis tends to be latent. The rest of the first part considers stigmas of malnutrition along the lines of loss of weight in the new-born, growth of cranial bones, and weight-height relationship and debility. He describes the hereditary factor in organ and tissue pathologic trends. Then he mentions the inheritance of infections and intoxications. He devotes a small paragraph to the hereditary manifestations that break out suddenly, often at a certain age. Finally, he describes the inheritance of the arthritic diatheses which Comby has described. He includes in this: seborrhea, eczema, asthma, obesity, gout, kidney and liver colic, hemorrhoids, migraine, rhinorrhea and bronchorrhea. He points to the fact that these various conditions seem to unwind like a ribbon from infancy with its eczema to old age with its arthritis deformans. The greater part of the book is devoted to the arthritic conception. This small volume gives some suggestion of the French point of view.

A Health Workbook for College Freshmen. An Orientation Course in Personal Home and Community Hygiene. By Kathleen Wilkinson Wootten M.A. (Mrs. H. Stewart Wootten) Professor of Health Head of Department of Health and Physical Education Georgia State College for Women Milledgeville Georgia Second edition Paper Pp 214 with Illustrations Milledgeville Ga. The Author 1934

This is an excellent and comprehensive college workbook on health, as its title indicates. Its forty-seven chapters proceed from a definition of health and an evaluation, through health status and health maintenance of the individual, and preventive medicine versus superstitions, to a study of the structure and functions of the human body, which begins in chapter 6 and goes through chapter 27, chapters on hygiene, beginning with 28 and going through 37, chapters on public health, beginning with 38 through 44, and then chapters on rest, leisure, and the achievement of individual health. The book is well documented and based on thoroughly authentic sources. The lesson helps in the way of activities and questions are excellent. One might be disposed to question the wisdom of such detailed health records as are presented in the self-rating health inventory, or score, except perhaps as a teaching instrument. Certainly no student should be advised to make any attempt at keeping the health rating in such detail after graduation. The exceptional completeness of the workbook makes it an excellent textbook on hygiene for college students.

Bright's Disease. A Clinical Handbook for Practitioners and Senior Students. By J. Norman Cruickshank M.C. M.D. D.Sc. Senior Assistant to the Muirhead Professor of Medicine University of Glasgow. Cloth Price \$3.75 Pp 208 Baltimore: William Wood & Company 1933.

The confused nomenclature and overelaborate classifications that are found on the subject of nephritis have created a field for simple and lucid textbooks on the subject. Larger treatises have recently been published that leave little to be desired in the way of clarity, but handbooks such as this have merit. They meet a practical need for practitioners in supplying a short account of the clinical application of modern views of the nature of Bright's disease. This book is in the nature of an outline of recent work on the subject. The clinical aspects are always featured and much of the detailed biochemical and experimental data has been purposely omitted. This book is not intended and should not replace some of the more comprehensive works on the subject but is a valuable adjunct to such books in providing a concise outline of the subject. The data in the book are clearly presented and well organized. The bibliographic references are well selected and are adequate for elaboration of the text. The book is well balanced in fundamental information and in clinical and pathologic description. Treatment receives adequate consideration and is logically presented. It is recommended to the practitioner who desires a concise, authoritative outline of modern information on Bright's disease.

Die Haut und Geschlechtskrankheiten. Eine zusammenfassende Darstellung für die Praxis. Herausgegeben von Prof. Dr. Leopold Arzt und Karl Zieler. Lieferung 8. Band IV. Syphilis der inneren Organe. Von Prof. Dr. Heinrich v. Hoesslin. Syphilis des Nervensystems. Von Prof. Dr. Heinrich Pette. Syphilis des Bewegungsapparates. Von Prof. Dr. Hermann Schlesinger. Syphilis des Auges. Von Prof. Dr. Georg Lenz. Paper Price 8 marks Pp 349-502 with 49 illustrations Berlin & Vienna: Urban & Schwarzenberg 1933.

Die Haut und Geschlechtskrankheiten. Eine zusammenfassende Darstellung für die Praxis. Herausgegeben von Prof. Dr. Leopold Arzt und Prof. Dr. Karl Zieler. Doppel-Lieferung 9/10. Band IV. Syphilis der inneren Nase des Kehlkopfes der Luftröhre und des Ohres. Von Prof. Dr. Heinrich Neumann. Syphilis der männlichen Geschlechtsorgane und Syphilis der inneren weiblichen Geschlechtsorgane mit Brustdrüsen. Von Prof. Dr. Moritz Oppenheim. Die angeborene Syphilis. Von Prof. Dr. Wilhelm Kertl. Die Bedingungen des verschiedenen Verlaufes der Syphilis. Von Prof. Dr. Alfred Stühmer. Erkennung und Untersuchung der Syphilis. Von Prof. Dr. Walther Schonfeld. Voraussage und Heilung der Syphilis. Von Prof. Dr. Karl Zieler. Die Behandlung der Syphilis. Von Prof. Dr. Paul Linser und Priv. Doz. Dr. Karl H. Vohwinkel. Die Behandlung der Syphilis mit unspezifischen Mitteln (Malaria-Rekurrens, Saprovia, Pyraler, Zittmann-Bekokt). Von Prof. Dr. Friedrich Berling. Durchführung der Allgemeinbehandlung im einzelnen bei den verschiedenen Formen der Syphilis. Von Prof. Dr. Paul Linser. Paper Price 14.40 marks Pp 593-804 with 59 illustrations Berlin & Vienna: Urban & Schwarzenberg 1933.

These volumes maintain the general trend of excellence of the previous contributions. The fundamental facts on visceral syphilis are presented by experts in the various departments of medicine. It is difficult to single out any one contribution for

special mention. The general principles of modern syphilotherapy are well discussed. A conservative estimate of the newer antisyphilitic remedies is given. The point of view of the student and the general practitioner is maintained.

Poetry of the Insane. Compiled by Dr. Charles E. Mayes. Fabrikhold. Price \$1.50 Pp 112 Baltimore: Waverly Press Inc. 1933.

The author, a physician with poetry as a hobby, has here collected some contributions by persons said to be insane, who handed him their poems while he was attending physician in the Illinois State Hospital and in various other institutions. The poems seem to establish his belief that the psychotic mind has all the hopes and aspirations common to the normal mind. These poems help the physician to an insight into the mental processes of those whom he attempts to heal. Certainly by any definition of poetry many of the items here included rank high. On the other hand, some of the rhymes rank with the output of children 12 years of age. For all interested in either psychiatry or poetry this collection will have a special appeal.

A German Doctor at the Front (Die Front der Ärzte). By Professor Dr. Wilhelm His. Translated from the original German by Colonel Gustav M. Blech. Medical Corps Reserve and Brigadier General Jefferson R. Kean. Cloth Price \$2.50 Pp 230 Washington D.C.: The Military Surgeon Army Medical Museum 1933.

The war experience of an illustrious German scientist and clinician is delightfully told in this book. It is not a pedantic narrative objectively committed to print but a human exposition of the author's experiences as medical inspector in Russia and Asia Minor. The facts as the writer observed them are presented without partisan bitterness but with a sympathetic understanding of loyalty and patriotism on both sides. Only a man with such a charming philosophy could have written such a book. Pursuing his medical labors in all possible situations, the author never lost his sense of humor. The story he tells will interest both the layman and the medical man. It is the physician, however, who will glean most from its pages. Mixed with the author's literary charm are medical gems on clinical medicine, epidemiology and sanitation. The settings for his narratives are unique and he has exhausted all their possibilities.

Tabulae biologicae periodicae. Herausgegeben von C. Oppenheimer und L. Plüncussen. Band II Nr. 3 (Tabulae biologicae Band VIII Nr. 3). Paper Price 55 marks complete volume Pp 241-320 Berlin W. Junk 1932.

Tabulae biologicae periodicae. Herausgegeben von C. Oppenheimer und L. Plüncussen. Band II Nr. 4 (Tabulae biologicae Band VIII Nr. 4). Paper Price 55 marks for 4 parts of Band II Pp 321-416 Berlin W. Junk 1933.

Tabulae biologicae periodicae. Herausgegeben von C. Oppenheimer und L. Plüncussen. Band III Nr. 1 (Tabulae biologicae Band IX Nr. 1). Paper Price 55 marks for 4 parts of Band III Pp 134 Berlin W. Junk 1933.

This compilation issued periodically in journal form, should be of value to research workers in experimental biology. It consists of brief reviews and tabulations presenting data on such subjects as muscle physiology, carotinoids, the photoperiodicity of plants, constants of arabacia eggs, derivatives of bile acids, saponins and proteases. These are chiefly in German, with an occasional section in English.

Behind the Screen. By Maurice Chidekel. M.D. Cloth Price \$2.75 New York: American Medical Publishing Company Inc. 1933.

Here in diary form is the record of the daily practice and interests of a physician. The book is much more likely to be enjoyed by medical readers than by the public for whom it is more likely to have a morbid interest than any other. The author has a sense of the dramatic as well as a sense of humor. The introspective character of his observations will make the book especially interesting to psychologists.

Medical Women of America. A Short History of the Pioneer Medical Women of America and of a Few of Their Colleagues in England. By Kate Campbell Hurd Mead. M.D. Cloth Price \$1 Pp 112 with illustrations New York: Froben Press 1933.

This is a painstaking study of the entrance of women into the broad fields of medicine. The book deserves to be more attractively presented as to both literary style and physical format.

Miscellany

MEDICAL EXHIBITS

At a Century of Progress International Exposition
Chicago, May 26-Nov 1, 1934

EDEN J. CAREY, M.D.
MILWAUKEE

The Chicago world's fair opens at 6 o'clock Saturday evening, May 26. The Hall of Science, dedicated last June, has nine acres of space in which exhibits of physics, chemistry, biology, mathematics, geology and medicine—both scientific and industrial—are displayed. The medical sciences occupy 40,600 square feet of floor space net (and the industrial section occupies 25,000 square feet). The exhibits of medical science will occupy a space 50 per cent greater than last year.

This is the second time in the history of international expositions in America that organized medicine, dentistry and pharmacy have presented to the public the story of their contributions to the progress of civilization.

The Medical Advisory Committee includes Drs. William Allen Pusey, chairman, Frank Billings (deceased), Ludvig Hektoen, Herman L. Kretschmer, Paul Nicholas Leech, Morris Fishbein, Arthur D. Black, Bert W. Caldwell, Julius Stieglitz, Benjamin H. Orndoff, A. S. Burdick (deceased), C. H. Searle, Lloyd Arnold and Franklin Martin and Messrs. Thomas McMahon, R. A. Whidden, Edwin R. Embree, Julius Riemen-schneider, H. C. Christensen, Will J. Cameron, Harry C. Phibbs, S. DeWitt Clough and George H. Merck.

The objectives of the exhibits on health education by the visual and auditory methods are: (1) to compare health conditions of a hundred years ago with those of today, (2) to instruct the public in the intricacy of the living human machine and to give warning not to meddle with it by dangerous self-medication, (3) to interest the layman in the scientific story behind the physician's services and opinions regarding health and sickness, (4) to show that compassion for suffering humanity and not commercialism ruled the lives of the great discoverers and practitioners of medicine, (5) to prove to the public that many chronic diseases such as cancer, tuberculosis, heart and kidney disorders, and diabetes, are preventable and, if detected early by a periodic health examination, are curable, (6) to show the layman the value of discrimination in selecting one to evaluate health and detect the presence of disease and that the knowledge and developed skill of the duly qualified doctor is the patient's only safeguard and bulwark in the prevention and cure of disease.

THE MEDICAL EXHIBITS LAST YEAR

The exhibit, to be effective, must first attract attention. Subjects of common interest, such as the development, structure and function of the human body, tuberculosis, infantile paralysis, heart disease, cancer, gonorrhea, pneumonia, Bright's disease and appendicitis, aid in drawing the public to a display. The method of presentation is vital, because an unfamiliar exhibit may have popular appeal if the unknown is presented in easily grasped stages of the known. This is exemplified by the urologic exhibit in which the significance of blood and pus in the urine is revealed by a series of panels showing the anatomy of the urinary organs.

An exhibit should be definitely arranged so that a personal demonstrator may not be required. On the other hand it is abundantly proved that a personal demonstrator giving short talks adds greatly to the attendance. The transparent man is a more popular object when the guides are delivering their three minute description than when no demonstrator is present. This likewise proves the value of movement when it may be accomplished, in drawing the attention of the public. When the transparent man is uniformly lighted, it does not have the appeal that it has when the organs from head to pelvis are

illuminated in rotation. The movement in the cancer exhibit, by the familiar growing flame of fire, has a value that is absent when the movement is stopped. The dynamic Dresden models and the teletractor for the blind are highly popular when the public can push a lever or press a button or can feel the vibration of the spoken voice on a diaphragm. The mechanism of the models must be substantial when dealing with large crowds such as those in the Hall of Science, or the models will become ineffective through being out of order half of the time. The personal demonstrator and the six foot book of maternal hygiene are attractive to the public. The combination of demonstrator, careful arrangement, adequate light, harmonious color and rhythmic movement in relation to a familiar subject are the qualities that attract attention.

After the attention has been arrested by a display, it is necessary to hold or retain the interest of the visitor. This is accomplished by simplicity of presentation. If the exhibit is easily seen and understood by a definite form, logical sequence and labels, short and clear, the observer usually lingers. If the exhibit is poorly lighted, cluttered hard to follow, and has lengthy labels finely written, the people pass it by.

The public is interested in reality. Actual specimens of human embryos and sections of the human body have more appeal than pictures. This is no more morbid curiosity on the part of the public than it is on the part of medical students. This holds true for the interest that diseased organs, such as cavitation of the lungs in tuberculosis, have for the lay observer. The public is interested in disease and the changes from health manifested by a diseased organ. The public is vitally interested in anything that may affect the human body in disease. The average man is no different than the doctor in this respect of interest, except in degree.

Next to the actual specimens, lifelike models, such as those showing the stages in the surgical removal of an appendix, hold the interest of the public. Dioramas of historic milestones in medicine are nearer to reality than pictures and therefore draw public notice. This is likewise proved by the sculpticolor, which has an effective emotional appeal in showing the physician's service to the sick child in the booth of 'The Family Doctor'. The musical accompaniment for 'The Family Doctor' at the bedside is well chosen and arouses the desired emotions of past sad memories in the mind of the visitor when the plaintive melody and minor chords of the adagio movement of Beethoven's Moonlight Sonata are vibrating. The sympathetic services of 'The Family Doctor' will linger long in the minds of grateful people, because adequate visual and auditory memories are established by this exhibit. I am not ashamed to say that each time in more than two dozen visits to this masterpiece a lump arose in my throat because the artistic combination of color, form and minor harmonic sound in a dignified environment appeared so perfect in conveying the meaning of the story of sadness of apprehensive parents and of the doctor's unselfish services at the bedside of a sick loved one. This exhibit appeals to the heart as well as to the mind. This may be beyond the pale of the so-called strict scientist, but there are many things in medical practice that are still beyond the analysis of science. The exhibit attracts the public, and that is proof enough of its success. The methods used are deserving of close study on the part of any scientist who attempts to tell his story to the layman. I am reminded in this connection of Leonardo da Vinci's statement that "the higher science develops, the nearer it approaches art, the greater the perfection in art, the nearer it approaches science."

The moving picture is used effectively in showing the operation where ether is first used as an anesthetic. This modality may be overused when the pictures are too long and inadequately labeled. This also holds for sound pictures. On the other hand, 'The Talking Tooth' in the dental exhibit uses sound in an effective manner.

When an exhibit may be prepared in order that a 12 year old child is able to grasp and study the demonstration, it is evidence that the exhibitor has a clear, firm and simple hold on the subject presented. If such a child is not attracted to the exhibit and his interest is not retained, it is usually a sign of inadequate thought and preparation on the part of the demonstrator or inadequate knowledge of the subject presented.

From the Medical Section, Department of Exhibits, A Century of Progress International Exposition.

Owing to lack of space, several illustrations have been omitted. The complete article appears in the author's reprints.

I know of nothing in which the gaps that still exist in medical knowledge, in spite of the brilliant advances made in the last hundred years, stand out so glaringly as in an exhibit on a subject on which medical science has not as yet shed its light.

In this second attempt in America to present medical science to the public, it is a conceded fact that the ones who benefit the most are the medical scientists who plan and prepare the exhibits. A good demonstration is an index that the teacher has a simple and true understanding of the relationships of the subject presented. When scientific objective knowledge cannot be conveyed in a clear-cut exhibit without complex terminology, it is a sign that knowledge is lacking.

An effective pedagogue in science is one who is a good demonstrator and allows ample means for the observer to exercise his faculties of sight, touch and hearing by actual participation in the demonstration. An effective exhibit is an index of a good teacher who knows his subject. The content of the exhibit may have a natural attraction. The observer tests his present knowledge in a satisfying way by recognizing and recalling it to memory. The exhibit may arouse curiosity by comparison and contrast.

If an exhibit is arranged in an effective manner it manifests the application of the laws of teaching. The student or observer must have the attention focused. It is up to the exhibitor to gain the attention in order to retain or focus it. If the content of the exhibit does not have natural appeal it must have a stimulated one in order to arouse the curiosity of the passer by. The exhibit must be definitely arranged and labeled in order to obtain the desired response on the part of the public. All annoyance and inconvenience such as poorly understood long technical words and inadequate light should be eliminated.

Everything exhibited should be a component part of a well coordinated whole in order that the layman may easily organize and integrate the meaning of the exhibit in his mind. The resultant clear-cut picture or story of the object of the exhibit is more valuable than a dictionary of words and proves that the exhibitor knows what he is trying to demonstrate. The greater the number of simple associations related to the main theme of the exhibit that are conveyed to the mind of the observer, the longer and more easily will the exhibit be remembered by those for whom it is prepared. An attractive exhibit that invites repeated visits has intrinsically the quality to be remembered because of the periodic review by the observer.

FUTURE OF MEDICAL EXHIBITS IN THE UNITED STATES

The medical exhibits in the Hall of Science at A Century of Progress exposition of 1934 represent three years of planning, assembling and constructing work on the part of the majority of the exhibitors. The expenses of preparing each exhibit and transporting it to Chicago are defrayed by the university, foundation or association sponsoring the display. A Century of Progress gives the space free of charge where an exhibit fits into the general plan and policy of development laid down by the Medical Advisory Committee.

The doctor needs public cooperation in conducting periodic health examinations in order to detect the early stages of tuberculosis, cancer, diabetes, goiter, heart vascular, kidney and certain mental diseases and physical deformities. Mass education of the public of what the doctor now has to offer may be effectively done by the exhibit method. The layman has proved that he is as interested in exhibits of health and disease as he is in museums of art and natural sciences.

The exposition of 1893 in Chicago left a heritage in the Field Museum of Natural History. Will A Century of Progress expositions of 1933 and 1934 point the way to the value and the establishment of a museum or hall of health? This is a question that organized medicine, dentistry and pharmacy should seriously consider. If the duly qualified physician, dentist and pharmacist, through their respective legitimate organizations, do not assume the role of teachers and interpreters in the mass education of an interested and eager public in matters of health and disease, who will?

POPULAR LECTURES ON MEDICINE IN HALL OF SCIENCE

Members of the Chicago Medical Society and the American College of Surgeons will give lectures each afternoon in the Hall of Science for the public on some popular subject on medicine and surgery.

THE FOREIGN EXHIBITS OF MEDICAL SCIENCE

The names of the contact officials or chairmen are mentioned after each institution or association. More than 500 medical scientists and physicians planned or executed certain parts of the exhibits. Grateful acknowledgment is here expressed to every one who aided to make the displays of the medical section a success.

England—The Wellcome Research Institution of London (Sir Henry Wellcome). The Wellcome Historical Museum has dioramas that illustrate epoch-making events in British medicine and surgery. The Wellcome Museum of Medical Science demonstrates by models, charts, diagrams and the like the causes, methods of infection, symptoms, prevention and treatment of malaria, trypanosomiasis, kala-azar, leprosy, plague and bilharziasis. The Wellcome Bureau of Scientific Research has contributions from the departments of protozoology, helminthology, bacteriology and experimental pathology. *Trypanosoma grayi* in the tsetse fly, series of worms parasitic to man and animals and Rift Valley fever—a newly discovered disease in British East Africa—constitute part of the exhibit. The Wellcome Entomological Field Laboratories and Physiological Research Laboratories have exhibits that deal respectively with the mosquito and with the physiologic, pharmacologic and serologic problems on the production of diphtheria, tetanus and other antitoxins. Diseases in animals such as lamb dysentery, dog distemper, braxy in sheep, canine jaundice, bacillary white diarrhea in poultry, tetanus in horses and fowl pox are presented by appropriate exhibits. A model of the Wellcome Research Institution in London, a model of the floating laboratory presented by Sir Henry Wellcome to the Sudan government on the Nile, and a model of the mobile field laboratory given to the British war office during the Great War are exhibited.

France—The Institut Pasteur (P. Lecomte du Nouy and W. Roux, deceased). An illuminated map of the world, 12 by 20 feet, shows the distribution of Pasteur institutes. By means of photographs in a space 12 by 20 feet, are effectively presented the life of Louis Pasteur, his work on crystals, the silkworm, fermentation in beer, wine and milk, and the relation of microbes in human and animal diseases, and the life and work of the pupils of Pasteur and their influence on human welfare.

Germany—The Robert Koch Institute (F. Neufeld). By means of models, photographs, portraits, drawings and charts are displayed the life and work of Robert Koch, who discovered the tubercle bacillus in 1882.

Public Health Exhibit of Berlin (von Drigalski). By means of models, charts and diagrams the recent advances of public health in Berlin are portrayed.

The Deutsches Hygiene Museum, Dresden, Saxony (exhibits purchased by A Century of Progress). The Transparent Man lent by the Mayo Foundation, is a life-size model made out of cello, a transparent material, to show all interior organs, illuminated in rotation, in their relation to the skin surface. Other dynamic models manifesting human structure and function, which may be motivated by the observer, are as follows: the different kinds of joints, nodding and rotating movements of the head, circulation of one blood corpuscle, cooperation of the diaphragm and lungs in respiration, abdominal breathing, showing the movement of the chest and diaphragm, movement of the rima glottidis, the larynx in a laryngopharyngeal mirror, formation of sounds, example of reflexion—knee jerk, torso of wooden man—sagittal section in eight parts, horizontal sections of wooden man, in fifteen parts.

Italy—Medical exhibits from the Italian government (E. Bompiani). By means of models, charts, photographs, appliances and the like are indicated the contributions of the fathers of medical science, such as those of Galvani, Malpighi, Morgagni, Spallanzani, Leonardo da Vinci and Vesalius.

Holland—Central Institute for Brain Research, Amsterdam (C. U. A. Kappers). With the aid of specimens, models, casts, charts and drawings the structure and function of the nervous system are demonstrated.

UNITED STATES EXHIBITS OF MEDICAL SCIENCE

AMERICAN COLLEGE OF SURGEONS (Franklin Martin)—By means of transparencies, models, dioramas, illustrated map

photographs and replicas, the progress of hospitals and surgery in America during the past century are depicted. A replica of the Lister exhibit in the Wellcome Historical Medical Museum is displayed. This consists of a diorama of the Lister Ward at the Glasgow Infirmary, photographs of Lister, his family, his degrees, letters patent, records, and the like, in show cases are displayed his pioneer experimental work on antiseptics and appliances used by him, and also replicas of furniture used by him.

AMERICAN HOSPITAL ASSOCIATION AND CHICAGO HOSPITAL ASSOCIATION (Bert W. Caldwell and Paul H. Fesler) — Photographs and charts showing a century of progress in hospitalization.

THE AMERICAN INSTITUTE FOR THE DEAF-BLIND (Robert H. Gault) — This exhibit relates to the development of methods of teaching the deaf and to the evolution of braille for the blind. A display of the Gault teletactor shows a method of enlarging the use of the senses of touch and vibration in connection with the education of the deaf. The apparatus consists of a microphone, a specially constructed amplifier and a vibrator or receiver. The visitor, resting his fingers on the receiver and speaking into the microphone, may feel his own voice. Similarly he may feel his companion's voice. Moreover, through a duplicate apparatus he may feel whatever programs are being broadcast from a given radio station. Charts and diagrams explain the fundamental scientific questions that are involved. There is emphasis on the essential similarity stimuli on the one hand by ear and learning their meaning, and receiving and interpreting the same stimuli, greatly amplified, by way of the organs of touch and vibration on the other hand. Photographs and occasional demonstrations illustrate the method by which the apparatus is being used toward promoting the interpretation of speech and improving the production of spoken language on the part of the deaf. Photographs and other forms of illustration show some features of various stages in the development of means of education of the deaf and the blind. Models and maps constructed manually by deaf pupils in the laboratory of the institute are used to suggest to the visitor the makers' scope of reading ability and skill in computation.

AMERICAN MEDICAL ASSOCIATION (T. G. Hull) — Dioramas, mechanical displays and transparencies are used to demonstrate progress in (1) medical practice, (2) medical care, (3) medical education and (4) health education. Bas-relief statuary portrays Aesculapius, the god of medicine, Hygieia the goddess of health, and Hippocrates, often called the father of medicine. There are contrasted the difficulties of the saddle-bag doctor with those of the physician of today with his numerous facilities. The many medical discoveries of the past century shown in brief review emphasize this point. It is also portrayed how a frequent physical examination tends toward good medical care and how self diagnosis and self medication result in poor medical care. A relief map of the United States has actual reproductions in miniature of the medical schools of the country. The role of the modern hospital as a place to which people now go to get well or to maintain their health is contrasted with that of a century ago. The correlation of community health and personal health is depicted by two new displays, and a question and answer service on health topics, so popular last year is continued and amplified this year.

AMERICAN PHARMACEUTICAL ASSOCIATION (H. C. Christensen) — As before, the exhibit will depict and dramatize the historical, educational and professional (scientific) phases of pharmacy. New features will emphasize the progress of American pharmacy during the past century, directly bearing on the service to the medical profession and the public at large. Visitors will be told of the development and standardization of drugs and drug preparations during the past hundred years, contrasting the old with the new, thus giving them a new conception of "the man behind the prescription case." One who enters the exhibit from the corridor will find at the left the Historical Rotunda with a series of seven brilliantly lighted recesses showing outstanding pharmacists and their contributions to pharmacy and medicine. In the center of the rotunda will be a reproduction of the famous Ebers papyrus, the earliest known book of remedies, which dates back to about 1500 B. C. Immediately behind the Historical Rotunda will be the exhibit of the United States Pharmacopoeia and the National Formulary. Here the story of these books of standards for drugs and medicines will be told both by displays and by an automatic pictorial

Part of the exhibit of the American Medical Association

machine. In the log cabin replica of the first apothecary established in Chicago in 1832 by Philo Carpenter, reproduced against the back wall of the exhibit space, will be housed an actual reproduction of an apothecary shop of a hundred years ago. Just to the right of the old apothecary shop and in striking contrast is located a modern pharmaceutical and chemical laboratory, in which will be conducted a program of demonstrations in prescription compounding, testing drugs for purity, examples of accuracy in weighing and measuring, and the like. In the next two recesses, the story of digitalis and ergot will be portrayed in dioramic views. The next recess will contrast the art in pharmacy a century ago with today by showing apparatus and utensils used during these periods. The growth and development of pharmaceutical education, legislation and service to the public will be depicted in the next group of exhibits. In the foreground will be a model of the American Institute of Pharmacy (pharmacy headquarters building). To the right of these will be a materia medica exhibit showing the evolution of medicinals. There will also be two displays in the corridor walls of the exhibit which will show drugs of the Bible, animal drugs, and the like.

AMERICAN SOCIETY FOR THE CONTROL OF CANCER (James Persons Simonds and A. H. Estabrook) — The purpose of this

exhibit is to demonstrate the fact that cancer, if discovered and treated in the early stages of the disease, is to a great extent curable. In a mechanical unit, cancer is compared to a fire. In its earlier stages cancer, like a small fire, can be controlled, but in its late stages, as in a huge conflagration, there is little hope for control. Material on the nature, incidence, prevention and treatment of cancer is presented in four dioramas. Models, drawings and charts are used to present the need of attention to all the early symptoms of cancer. The history of the treatment from ancient times and the present methods of treatment by surgery, x-rays and radium are depicted.

AMERICAN UROLOGICAL ASSOCIATION (Herman L. Kretschmer and George C. Smith) — With the assistance of drawings, charts and models is emphasized the need of consulting a physician when blood and pus are in the urine. Tuberculosis, tumors, stones of the urinary tract and disease of the prostate gland are developed in a general way with a panel devoted to each disorder. The development of urologic instruments is presented with the aid of Mueller of Chicago.

AMERICAN VETERINARY MEDICAL ASSOCIATION (H. Tren-ton Hoskins) — The theme of the exhibit will be expressed in a series of eight dioramas each one depicting an important activity of the modern veterinarian. The area of each diorama will be approximately 3 by 3 feet, with a height of about 2½ feet. These will be arranged in a straight row against the back wall of the booth. The front of each diorama will be glazed and each one will be dust proof and properly illuminated. Above each diorama will be a sign carrying a brief legend, such as Small-Animal Practice, Country Practice, Military Medicine, Laboratory Research, Field Investigations, Education, Public Health, Biological Manufacturing. In addition each diorama will include a small card carrying a legend, such as "Intelligent treatment is based on correct diagnosis—not guesswork." "A prosperous agriculture is dependent on a productive animal industry, which in turn is dependent on a competent veterinary service." "The up-to-date veterinarian practices prevention rather than cure." "Veterinary inspection makes your meat and milk safe."

The wall space not occupied by the dioramas will be utilized to display appropriate photographs, statistical charts and other material of a purely educational character. There will be a model of a cow, showing what takes place when the animal swallows a foreign body, such as a nail resulting in the condition known as traumatic pericarditis. A small exhibit of animal parasites will be shown.

CLEVELAND CLINIC FOUNDATION (George W. Crile) — Motion pictures present the discovery of the circulation of the blood by Harvey in 1628, the development of modern methods of transfusion and the formation of autogenous cells. The history of blood transfusion is shown by the use of actual instruments with the aid of Mueller of Chicago and Kimpton of Boston. The physiologic interrelations of the thyroid, suprarenal, pituitary and sex glands are illustrated by specimens, charts, models and drawings. The history of the roentgen ray consists of an x-ray apparatus and tube used in 1896 and a number of roentgenograms, books and tubes made within a few weeks after the discovery of the x-rays in 1895. On a mechanical device a number of pictures are shown in succession which will contrast early and present-day x-ray tubes apparatus and pictures.

COMMITTEE ON DIABETES (Rollin T. Woodratt and Morris Fishbein) — An exhibit on diabetes will show the public what the disease is, its causes and its curability with diet and insulin. In spite of the fact that now, since insulin has become available, no one with diabetes need die of the disease, the mortality rate in this country has been climbing rapidly. Many do not know about insulin, many do not know how to use it, some refuse to try it and some cannot afford it. The exhibit will show the principles of dietetic care and will give some idea of the use of insulin and of the prevention of those injuries to the feet and legs which often have tragic consequences to the diabetic patient. The exhibit will carry a message of hope and encouragement to the patient with diabetes. There will be pictures of patients strong and well after years of treatment. There will be representative diets shown in wax and also samples of insulin in the several dosages.

CHICAGO BOARD OF HEALTH (H. N. Bundesen) — With apparatus, stereopticon lantern slides, charts and diagrams, the history of the control of preventable diseases in Chicago during the last hundred years is disclosed. Health educational work along various lines is indicated.

DENTAL HEALTH EXHIBIT (Arthur Black) — The dental health exhibit of 1934 points the way to the prevention of dental ills and to better health through the simple means of proper care of the teeth from early childhood. The major exhibits are:

1 **Nature, Builder of Teeth** A twelve minute talking motion picture shows the development of the teeth, jaws and face from birth to the age of 18 years. This is a striking illustration of the relation of the teeth to facial symmetry and beauty. Instructions regarding the development of the teeth through proper diet and their care during childhood are presented in a twelve minute discussion by phonograph transcription immediately following each showing of the film.

2 **The Talking Tooth** A framed ground glass, 10 feet high by 4 feet wide, behind which there are 1,164 small electric lamps arranged in an elaborate system of shadow boxes, portrays in brilliant colors the beginning and progress of a cavity in a molar. The tooth tells its own story by a phonograph which operates 175 lighting changes. Directions for preventing serious decay are given.

3 **Tooth Brushing** A motor-driven, revolving, hexagonal exhibit with six aluminum heads and hands continuously demonstrates proper methods of brushing the teeth.

4 **Mastication** This motor driven exhibit shows the jaw movements of a tiger, representative of meat-eating animals, of a mountain sheep, representative of plant feeders, and of man illustrating the combined motions of the other two. There is also a dentist's instrument used in arranging artificial sets of teeth so that they are exactly adaptable to the jaw movements of each person.

5 **George Washington's Artificial Teeth** These are exhibited in a steel pedestal with a nonshatterable glass top and are accompanied by photographs taken before and after the natural teeth were extracted, which show the marked change in facial contour and expression.

6 **Pylorrhea** A framed ground glass 10 feet high by 4 feet wide illustrates by the reflection of 1,178 small electric lamps the gradual destruction of the gum and other tissues in case of pylorrhea. The process is described by a phonograph, which also operates the lighting circuits.

7 **Professional Dental Education** A beautiful model of the building occupied by the first dental school founded in Baltimore in 1840, is shown alongside a section cut through a modern dental college building, which shows a separately equipped and illuminated miniature room for each course of study. Accompanying this is an exhibit of early dental books from 1530. Description is given by phonographic transcription.

8 **A Century of Progress in Dental Service** A revolving stage shows dental office equipment of 100 years ago, fifty years ago and today, also an office equipped especially for children. The various periods have been worked out to the most minute details. Description is given by phonographic transcription.

9 **Facial Beauty** The effect of dental conditions on facial beauty and expression is shown by about 100 plaster models of faces made before and after various methods of treatment, consisting principally of the correction of irregularities of children's teeth, of the use of properly designed sets of artificial teeth and plastic operations to remove facial scars and other defects for adults.

10 **Balanced Diet** The importance of proper diet in building and maintaining sound teeth throughout life is demonstrated in a large alcove window.

11 **Paintings, Prints and Cartoons** Sixteen oil paintings and drawings by famous artists from 1610 to 1879 are shown.

12 **Bronze Tablets** Twenty-one bronze tablets recite noteworthy achievements of famous dentists from 1520 to 1933. There are about 100 other exhibits in show cases, consisting of many curious old instruments used during the past 200 years, good and bad forms of tooth brushes, the first demonstrations of 'laughing gas' and ether for surgical operations.

by two dentists, and cuneiform tablets from ancient Assyria describing dental treatment 2,600 years ago, facial models of cancer and syphilis of the mouth and face

CHICAGO GOODWILL INDUSTRIES (W C League)—The equipment consists of a large floor loom, table loom, bicycle saw, work bench and table. These pieces are arranged in a semicircle and will constitute the major part of the display to demonstrate treatment. Patients from the Goodwill Workshop receive this treatment under supervision two hours daily.

CHICAGO MEDICAL, DENTAL AND ALLIED SCIENCE WOMEN'S ASSOCIATION (Katherine K True, Lena K Sadler and Bertha Van Hoosen)—By means of an automatically operated book 6 feet high and 4 feet wide, there are questions and answers on maternal hygiene. With the aid of artistic paintings and models, the relation of food, clothing and appropriate environment for the expectant mother is shown.

CHICAGO MUNICIPAL TUBERCULOSIS SANITARIUM (Allan J Hruby)—The central object in this exhibit will be a mural in oils measuring 8 by 5 feet. In this painting the central figure in the middle foreground is the "Sower of the Seed." The figure of the sower is taken from an actual portrait of an advanced tuberculosis patient at the Sanitarium. It shows the typical configuration of the advanced consumptive and is represented as advancing toward the foreground somewhat in the manner of Millet's sower with hand extended broadcasting the seed. Behind him is the desert trail over which he came, bones and skeletons representing the tragedy of tuberculosis. In the right foreground is a female figure representing humanity prostrate and passive typifying the passive attitude of public health authorities in general toward tuberculosis. In the left foreground is the figure of the mother surrounded by her children, her arm extended in a protective and defensive attitude. Framing the painting is an encircling branch of weeping willow, typifying again the tragedy of tuberculosis. In the left background represented in the clouds is Father Time sharpening his scythe against the harvest which he knows will come. The theme of the whole picture portrays tuberculosis as an infectious and contagious disease. The picture will in turn represent the central motif of the entire exhibit. The purpose is to give the thousands of visitors at the Century of Progress the concept that tuberculosis is actually and beyond doubt a contagious disease in the same sense that smallpox, leprosy, scarlet fever and other diseases are. To emphasize further the infectious nature of tuberculosis, several microscopes will be on hand under the supervision of a laboratory attendant. Slides will be prepared showing the tubercle bacilli in various concentrations, and the people as they pass will have an opportunity to see for themselves the causative organism of tuberculosis. Leading on from etiology to pathology, a dozen or two pathologic specimens suitably prepared will be on exhibit. These specimens will show changes in the lung structure due to tuberculosis and will be sufficiently distinctive to be readily intelligible to the lay audience. Furthermore, a large double rack, showing a series of x-ray plates, will be on exhibit. These plates, of interest both to the profession and to the public, will show in series the gradual development in the lung of the tuberculous lesion. In this section also will be several plates showing vividly the effect of pneumothorax on the lung and showing the various degrees of collapse. As explanatory of the tuberculosis problem and its seriousness and magnitude, even at the present time, a series of charts will be on hand, showing the morbidity and mortality of tuberculosis even today in this city and throughout the country. Other charts will be prepared showing the cyclic decrease in tuberculosis mortality down through the years. As a final measure of education it is proposed to have hundreds of instructive bulletins to be distributed free of charge to such as may be interested. A nurse or physician or both will be in continuous attendance to answer questions and to give detailed information concerning work of the Municipal Tuberculosis Sanitarium. The exhibit will emphasize the contagious nature of tuberculosis and lays stress on the public health measures necessary to prevent it.

CHICAGO RAPID TRANSIT COMPANY (Hart E Fisher)—An exhibit will be presented on the evolution of resuscitation showing the methods both manual and mechanical from the early

ages down to the present through the medium of charts, transparencies, drawings and photographs. These are to be placed on one of the end walls in the exhibit space. On the opposite end wall will be displayed by charts, photographs and working models the scientific exhibit of Dr Albert S Hyman of the Witham Foundation of New York, showing the artificial pacemaker for electrical stimulation of the heart in artificial respiration. At the back wall of the exhibit is to be placed a woodland scene through the use of art paper and painting. This wall will also carry the charts on electrical accidents and resuscitation with photographs showing the activities of the medical department in its research on electrical shock, burns, and its twenty years of periodic medical examination. In addition will be charts showing the research work on reaction time and mental testing of employees. On the floor, half of the space will be devoted to the showing of two working models of the adult and infant Drinker respirator, with manikins lent by Warren E Collins, Inc., of Boston. There will also be two Emerson respirators, adult and infant, with working manikins lent by J H Emerson of Cambridge, Mass. The medical department of the Chicago Rapid Transit Company will exhibit one portable hand operated respirator and one adult respirator, a Panis respirator, the inversion method, the hanging tree method, the barrel method, the lungmotor, both adult and infant, the pulmotor, and the Lyon breathing apparatus. Also on exhibition will be an animated life size working model of the Schaefer prone pressure method, which is lent by the United Power and Light Corporation. The story will portray research in resuscitation, electrical accidents, periodic medical examinations, and mental and reaction time testing in the form of an educational feature for the general public.

CHICAGO MEDICAL SOCIETY AND WOMAN'S AUXILIARY (H N MacKechnie, C H Phifer and Sophia Brumbach)—The history of the Chicago Medical Society and related medical progress in Chicago are presented. Desks for registration of visiting physicians and medical auxiliary are provided.

CHICAGO ROENTGEN SOCIETY (Hollis E Potter and Benjamin H Orndorf)—The plan of the Chicago Roentgen Society exhibit is to show the average visitor the wide scope of usefulness of x-rays in diagnosis, together with something of the methods employed. The basic exhibit will be films showing twenty-five diseases selected because of their pathologic importance and because of x-ray value in their diagnosis. Each disease will have twenty-five 8 by 10 inch film copies showing the typical and variables. Each disease unit will be introduced, explained and oriented on a few panels adapted to the average lay intelligence. For showing something of the methods of roentgen diagnosis, a running series of slides will be projected from a Ballopticon on a transparent screen. For especial interest there will be a full sized man shown by reflected light on semitransparent paper behind and through which by pressing a button there will show at will ten roentgenograms of ten different parts of the same man. A second figure is planned on the same principle except that the light alternation is automatic and the whole figure will show by transmitted light through a full length x-ray film behind. All films used for the exhibit will be on acetocellulose (safety) base to avoid fire hazard.

HENRY FORD HOSPITAL (Frank W Hartman and Roy D McClure)—The exhibit of the Henry Ford Hospital, Detroit, will have models, appliances, transparencies, photographs and photomicrographs showing the tannic acid treatment of burns and oxygen therapy in pneumonia.

HOT SPRINGS NATIONAL PARK (Thomas J Allen Jr)—The exhibit of Hot Springs National Park is planned to show what the United States government is doing at that location to develop and operate an area for the use of the public in either regaining lost health or retaining and lengthening the period of good health. This being the only government-controlled area of its kind it is an individual feature of government operations. The exhibit in addition to its health features, is designed to show the history connected with the 102 years of government control of the resort, this period in itself being a century of progress in the use and application of natural hot mineral waters. The presentation is built around the large diorama feature at

the end of the space, in which a natural hot mineral spring arises from tufa rock that actually had been formed around one of the real springs in the park. The diorama shows a model of a portion of the famous Bath House Row in Hot Springs National Park, with a background of one of the wooded mountains of the park. In one upper corner of the background is a symbolic picture representative of an old Indian camp recalling the use of the spring water by the wandering Indian tribes in early days. The side walls of the exhibit are to be covered with photographic transparencies, on one side to be historical presentations from 1832 to more recent times and on the opposite side to be photographic transparencies of the modern use of hot water in the different bath halls and photographs of bath house exteriors. Descriptive matter, concise but interesting and explanatory, will be interspersed.

INSTITUTE OF MEDICINE OF CHICAGO (medicolegal, Oscar T. Schultz)—It is the aim of the medicolegal exhibit of the Institute of Medicine of Chicago to portray that (1) under the present organization of society it is necessary for the government to make official investigation of certain deaths and that such deaths constitute a not inconsiderable proportion (18.8 per cent) of all deaths that occur in a populous community, (2) the deaths that must be officially investigated fall into the four main classes of homicide, suicide, accident and sudden death, (3) the government has set up two different types of agency for such investigation, the coroner's office and the office of medical examiner, (4) impartial and thoroughly scientific investigation is important to society in the administration of justice and in the adjudication of claims for insurance and workmen's compensation. In a 20 by 40 foot space it is proposed to carry out this aim as follows. At the center of the forty foot wall space will be a diorama which will symbolize the tragedy and enigma of death. This will be flanked on each side by two smaller dioramas portraying graphically the four classes into which the death may fall: homicide, suicide, accident and sudden death. On each side of the diorama unit will be a painted panel. On one side this will be symbolic of the medical examiner system, showing a modern autopsy room, with a shrouded body and a gowned figure of a physician ready to begin his examination, in the background will be sketches indicative of the scientific procedures that a proper examination must make use of: pathology, bacteriology and serology, chemistry and toxicology, and microscopy. The panel of the opposite side will be symbolic of the coroner system. It will depict the usual type of coroner's jury being sworn in for the inquest in the presence of the dead body as the law requires. In the background, corresponding to the scientific procedures in the other panel, will be sketches portraying coroners' juries at different periods in history, the object being to illustrate that the office has not changed much since its earliest days. This graphic material will in turn be flanked on each side by a lettered panel giving succinctly the essential features of the two systems in use in this country. This will include such data as origin, mode of selection, tenure of office, qualifications, duplication of other agencies of government and cost. On the side walls will be diagrams showing the organization and relationships within the judicial administrative system of the continental medicolegal system with its institute of legal medicine. A similar diagram will show the same features of the two American systems. On each wall there will be a case containing a few well selected specimens to illustrate without unnecessary gruesomeness, some of the features of the different kinds of death that must be officially investigated. With the specimen will be a sketched-in background to illustrate either some feature of the mode of death or the scientific procedure necessary to detect the cause of death.

LOYOLA UNIVERSITY OF CHICAGO (J. M. Essenberg)—The exhibit is designed to show the contribution of Loyola University to modern methods of teaching the structure of the human body, anatomy, and its development: embryology to medical students. It consists of a large collection of human embryos and of several series of sections of the adult human body. The embryology collection is composed of carefully selected embryos and fetuses varying in age from a few weeks after conception

to the time of birth. Transparent or "x-ray" preparations of actual babies are included to show the development of internal organs. Special attention is called to the envelopes or membranes that surround the growing embryo. The origin, development and structure of the afterbirth is made clear by the use of different colors. Explanatory notes are attached to each preparation. The structure of the adult body is illustrated by sections or sectional anatomy, as it is called in medicine. Sections through all parts are displayed, and there are three series of these representing planes at right angles to each other. Every organ of considerable size is shown, and colors have been added to make structures easier to distinguish. Each section is mounted in a specially designed aluminum case with glass on both sides. This exhibit aims to give to visitors first hand information as to the complexity, delicacy, dignity and beauty of our own body. It tries to supply the physical basis for the command "know thyself."

MARQUETTE UNIVERSITY AND THE MILWAUKEE COUNTY HOSPITAL (Francis D. Murphy and Joseph Grill)—The display consists of about 200 specimens illustrating the various types of Bright's disease. Each specimen is accompanied by photomicrograph pointing out the important lesion to be demonstrated. In addition, the case report is attached to each specimen. The histologic aspect of the subject will be illustrated by numerous photographs and life histories of the important contributors to the entire subject of Bright's disease. Original manuscripts of the earlier writers will be arranged in the booths. The object of this display is to emphasize the importance of Bright's disease as a cause of morbidity and mortality and to point out methods that are to be used in the prevention of chronic nephritis. At the same time there are many self-explanatory charts, which point out the most important features of the early stages of the various forms of Bright's disease. In the charts, which are framed and placed above the specimens, are given the chief causes and means of prevention of Bright's disease. It is generally accepted that chronic nephritis is a disorder that arises from attacks of acute nephritis which have occurred many years before and have gone unhealed. When chronic nephritis or Bright's disease develops, but little can be done for the patient, on the other hand, if the disease is recognized and vigorously treated in the acute or transitional stage following the acute, much can be done to prevent the development of the chronic phase.

MAYO FOUNDATION (Walter Alvarez)—This institution is developing three themes, namely, diseases of the digestive tract, the thyroid gland and the sympathetic nervous system. The information is presented with the help of transparent photographs, wax models, charts, motion pictures and lantern slides. A model of an x-ray laboratory and of Dr. Cannon of Harvard, in 1896, making the first roentgen studies of the stomach are shown. A collection of roentgenograms, wax models and actual gallstones illustrates the commoner lesions of the digestive tract, and a diagrammatic model of the stomach and the intestine indicates the situation of these lesions in the body. A large model of the thyroid gland in wax and seven lifelike wax masks display the appearance of patients with the different types of goiter and thyroid gland deficiency. The successive stages are shown in the extraction of a few grains of thyroxine, the active constituent of the thyroid gland, from 25 pounds of raw material. Large transparent photographs of dissections of the sympathetic nervous system are presented so as to orient the lay visitor. A large electrical thermometer enables visitors to measure the temperature of their hands and an electrical thermometer enables them to see how steady their nerves are.

NORTHWESTERN UNIVERSITY MEDICAL SCHOOL (James P. Simonds, Leslie B. Arey and Andrew C. Ivy)—The exhibit will consist of 1. Charts, photographs, drawings and actual specimens illustrating the routine uses of animals in laboratories and the discoveries that have been made from experiments on them. Under the general title "Contributions of Animals to Medical Science and Human Health" each species of animal will be given credit for its contribution. 2. A series of photographs illustrating changes in methods of illustration in teaching anatomy under the general title "Forty Centuries of Anatomical Illustration." 3. A series of photographs and drawings illustrating progress in neurologic technique and in

neurologic surgery, dermatology and ophthalmology 4 A series of charts, photographs, drawings and specimens illustrating infections of the hand, use of mucin in the treatment of gastric ulcer, distended dried stomach and intestine to show the structure of the gastro intestinal tracts of different animals, pathologic specimens with explanatory notes illustrating some of the more common diseases 5 Anatomic models 6 The history of Northwestern University Medical School 7 A display of charts showing the disease transmitted from animals to man

OVARIAN HORMONES AND HUMAN EGGS (Edgar Allen and G W Corner)—Eggs of Man and Monkey This exhibit will display photographs of human and monkey eggs as shed from the ovaries and recovered from the tubes at operation, human and monkey eggs in large follicles in the ovary, and the time of ovulation in the menstrual cycle

Ovarian Hormones Hormones of the ovary—theelin, corporin or progesterin, and relaxin—the first from the follicles, the others from the corpora lutea The reactions that these hormones have on the genital organs in rats, rabbits and monkeys, and a brief indication of their clinical possibilities Samples of chemical fractions during the process of their extraction and crystalline preparations where available

Panels 1 Method of recovery of ova from the tubes and test for patency of the tubes in patients at operation 2 Appearance of the living egg and its finer structure in section correlated with corpora lutea from which they have been extruded 3 Additional photographs of eggs and a chart showing the time of ovulation in the menstrual cycle in women 4 Human eggs from large follicles in the ovary in various stages of growth and degeneration 5 Sections of ovaries and eggs of the monkey 6 A chart of ovulation time and cycle length in the monkey 7 Growth of follicles and other transformations in the ovaries of the pig during the estrous cycle 8 Selective elimination of eggs during the course of their development in the pig ovary, and the premature induction of puberty in young rats by injections of hormones 9 The formation of new eggs in the ovaries during adult life 10 Animal reactions to the ovarian hormone theelin, especially the growth reaction in the genital tract, and mating instincts produced by substitution of theelin for the endocrine function of the ovaries 11 The effects of theelin on the "sexual skin," vagina and cervix, in the monkey 12 Reactions of the genital organs of immature monkeys to theelin 13 Effects of ovarian hormones on the wall of the uterus where the embryo implants, the experimental production of menstruation 14 Effects on the mammary glands, including the skin of the nipples 15 A few major steps in the purification and crystallization of theelin, showing samples of the extract at different stages 16 The hormone of the corpus luteum and experiments showing its effect on the uterus and the first successful replacement therapy which permitted a mother without ovaries to bear young successfully through a gestation period of normal length 17 and 18 The development of the mammary gland and its dependence on hormone stimulation for growth and function 19 Biochemistry and animal reactions of corpus luteum hormones in rabbits, guinea-pigs and monkeys

THOMAS HENRY SIMPSON MEMORIAL INSTITUTE FOR MEDICAL RESEARCH (University of Michigan, Cyrus C Sturgis, Raphael Isaacs)—The exhibit will consist of a series of charts and models arranged along the walls of the exhibit booth to illustrate (1) what blood is, (2) its amount and components, (3) how and where it is made, (4) its various functions, (5) its variations in simple disease processes, (6) its relation to food, (7) instruments used for the study of blood, (8) blood transfusion The exhibits are so arranged that a person wishing to gain an elementary knowledge of blood can start at chart 1 and advance through the others The technic of blood transfusion as well as some other details will be shown by wax or other models representing an actual hospital scene It is possible that a rotating device to illustrate transportation of oxygen by red corpuscles from the lungs to the organs may be shown

U S PUBLIC HEALTH SERVICE, Federal Building (J G Townsend)—This extensive exhibit occupying more than 2 500 square feet, shows the progress made in public health and

sanitation since the establishment of the service and is presented in divisions as follows Marine Hospital Division, Division of Scientific Research, Division of Interstate Quarantine, Foreign and Insular Quarantine, Mental Hygiene, Venereal Diseases, Charts and Graphs, Miscellaneous There is exhibited an old style medical kit and a modern ship's medicine chest There are models of a modern milk plant and of an approved schoolroom with all modern facilities The recent work on pellagra, tularemia, undulant fever, typhus fever, spotted fever and psittacosis (parrot's disease) are clearly presented The brilliant control of smallpox by vaccination since the time of Jenner, 1796, typhoid by inoculation and diphtheria by toxin-antitoxin are shown by charts, models and posters There will be models of the septic tank and water purification plant, and of evolution of water containers on common carriers made by Dr Crowder of the Pullman Company By wax models, charts and photographs, the recent work on trachoma is presented There are models of a disinfecting plant, a rat-proof wharf, a rat-proof warehouse, a rat-proof vessel, and a large map of the Western Hemisphere showing airplane routes to the United States, time of flight, and infected yellow fever areas There is a large illuminated world map showing the incidence and death rate of smallpox and the practical obliteration of this disease by vaccination

UNIVERSITY OF CHICAGO (E L Compere)—This exhibit has been prepared for the purpose of educating the lay public in the need for providing adequate care for the more than 300,000 crippled children in the United States It is further hoped that the exhibit may emphasize, both to the lay public and to the physician, the fact that many of these crippled children can be rehabilitated to a degree of functional usefulness and self support who in the past may have been considered hopeless The scientific part of the exhibit emphasizes the development, structure, function and derangement of the human spine, with particular emphasis on the disks found between the vertebrae With the aid of models, photographs, roentgenograms and photomicrographs, the scientific evidence is presented In a diorama are shown the surgical procedures that were practiced by the southwest Indians of the United States before the time of Columbus In another diorama, a modern orthopedic ward of six beds is presented By motion pictures, the results of treatment of acute anterior poliomyelitis are projected for the observer The treatment of other diseases of the bones and joints is illustrated with transparent and colored photographs on transilluminated panels

UNIVERSITY OF GEORGIA SCHOOL OF MEDICINE (George L Kelly, M D, and Eugenia Long Harper)—Memorial exhibit to Crawford Long, the discoverer of ether anesthesia, in Jefferson, Ga, March 30, 1842 Statue, office desk used by Crawford Long, photographs and photostatic copies of letters and evidence of Crawford Long's priority in the discovery of ether anesthesia

UNIVERSITY OF ILLINOIS COLLEGE OF MEDICINE, COLLEGE OF DENTISTRY, DEPARTMENT OF ANIMAL HUSBANDRY, and the ILLINOIS DEPARTMENT OF PUBLIC HEALTH (D J Davis and Tom Jones)—This exhibit constitutes 2,200 square feet and is composed of dioramas, models, transparencies, charts, drawings and specimens showing the relation of focal infections to systemic diseases hay fever, tuberculosis, pneumonia, hemophilia and rabies The Illinois Department of Public Health has dioramas on milk production and distribution, contrasting insanitary methods with modern sanitary ones Health conditions of 100 years ago are shown in contrast with those of today, bringing out the effective means employed of purifying the water supply and of the disposal of waste material There are included exhibits on the heart, epidemic encephalitis and amebic dysentery

UNIVERSITY OF WISCONSIN (C R Bardeen)—Beaumont exhibit of books, photostats, photographs and charts of the epoch-making work on gastric digestion published in 1833 This is the centennial of the publication of the work of the first American physiologist, conducted on the French voyageur Alexis St Martin, who had a permanent gastric fistula, the result of an accidental gunshot wound This investigation was conducted in the territory of Wisconsin and Michigan

561 North Fifteenth Street

Medicolegal

Practice of Medicine by Layman Through Licensed Physician Unlawful, Urinalyses and Blood Pressure Tests as the Practice of Medicine—Granger, a layman, conducted a so-called health audit service. For a fee he undertook to make for individual subscribers urinalyses and blood pressure tests and to report the results. He employed a licensed physician Dr. Grave, to make the urinalyses and to report to him, with such recommendations as Dr. Grave thought proper as to the subscribers' health habits. Granger passed on to the subscriber the information he received from Dr. Grave. Apparently, Granger himself made the blood pressure tests. Under orders of the Minnesota board of medical examiners Dr. Grave refused to continue the making of urinalyses under his contract, and Granger sought by injunction to restrain such interference by the members of the board. They entered a demurrer, contending that Granger's activities constituted the practice of medicine, that his contract with Dr. Grave was therefore illegal, and that consequently it was not entitled to protection by a court of equity. The trial court sustained the demurrer and Granger appealed to the Supreme Court of Minnesota.

Granger denied that his activities constituted the practice of medicine, laying emphasis on the fact that he never recommended the taking of medicine or any treatment, but only suggested to subscribers whose reports were repeatedly abnormal that they consult their physicians. But regardless of whether or not medicine was prescribed the court was of the opinion that Granger was practicing medicine. Diet, exercise and mode of living were prescribed and they are agencies for the relief of disease. The science of diagnosing human diseases and ailments has come to be a distinct branch of the medical profession. The diagnostician limits his efforts to the discovery of the disease or ailment, leaving treatment to some other physician or surgeon. A physician who thus applies his learning and energies in the diagnosis of disease is engaged in the practice of medicine even though he prescribes no drug and administers no specific treatment. *State v. Rolph*, 140 Minn. 190, 167 N. W. 553, L. R. A. 1918D, 1096.

If Dr. Grave was practicing medicine in what he did and in determining for Granger whether the subscribers' urine was normal or abnormal, then, in the opinion of the court, Granger was practicing medicine when he passed on to the subscriber the result of the analyses and Dr. Grave's advice. Granger was as much practicing medicine in employing Dr. Grave to do this work for him as he would have been if he himself had attempted to make the urinalysis, as he in fact did make the blood pressure tests. To pass on to the subscriber advice as to whether or not the tests indicated a normal or abnormal condition and whether or not the subscriber should consult his physician or be content with the advice which Granger himself might give in regard to diet, exercise and mode of living was practicing medicine.

The Supreme Court pointed out that a corporation or a layman could not practice law by employing a licensed attorney, for the profit of the corporation or layman employing him to act as attorney or counsel for others. *In re Disbarment of Otterness*, 181 Minn. 254, 232 N. W. 318, 73 A. L. R. 1319. The court was convinced that it was improper and contrary to statute and public policy for a corporation or layman to practice medicine in a similar way. Dr. Grave's obligation under his contract was to Granger, not to the subscribers to the health audit service. The law intends that the patient shall be the patient of a licensed physician, not the patient of a corporation or layman. The obligations and duties of a physician demand no less. There is no place for a middleman. In this rule the court could see nothing to prevent life insurance companies from furnishing free examinations to their policyholders, since insurance companies charge no fee and make the examinations in promoting the reduction of insurance hazards. The court could not see any objection to the employment by physicians of technicians and other experts, leaving the results of the work of the

technician or expert to be interpreted by a physician as a help to diagnosis.

Since the contract between Granger and Dr. Grave was in furtherance of Granger's violation of law, it was illegal, against public policy and void, and no injunction could be issued to prevent interference with it.—*Granger v. Adson et al* (Minn.), 250 N. W. 722.

Society Proceedings

COMING MEETINGS

- American Medical Association, Cleveland, June 11-15. Dr. Olin West, 535 North Dearborn Street, Chicago, Secretary.
- American Academy of Pediatrics, Cleveland, June 11-12. Dr. Clifford G. Grulee, 636 Church Street, Evanston, Ill., Secretary.
- American Association for the Study of Gonorrhea, Cleveland, June 9. Dr. J. R. Yung, 670 Cherry Street, Terre Haute, Ind., Secretary.
- American Association for the Study of Neoplastic Diseases, Baltimore, June 21-23. Dr. Eugene R. Whitmore, 2139 Wyoming Avenue, N. W., Washington, D. C., Secretary.
- American Association of Industrial Physicians and Surgeons, Cleveland, June 11-12. Dr. Volney S. Cheney, Armour and Company Union Stock Yards, Chicago, Secretary.
- American Association of Medical Milk Commissions, Cleveland, June 11-12. Dr. Harris Moak, 360 Park Place, Brooklyn, Secretary.
- American Association on Mental Deficiency, New York, May 26-29. Dr. Groves B. Smith, Beverly Farms, Godfrey, Ill., Secretary.
- American Bronchoscopic Society, Cleveland, June 11. Dr. Louis H. Clerf, 110 South 10th Street, Philadelphia, Acting Secretary.
- American Clinical and Climatological Association, Toronto, Canada, May 21-23. Dr. Francis M. Rackemann, 263 Beacon Street, Boston, Secretary.
- American Dermatological Association, New York, June 7-9. Dr. William H. Cuy, 500 Penn. Avenue, Pittsburgh, Secretary.
- American Gynecological Society, White Sulphur Springs, W. Va., May 21-23. Dr. Otto H. Schwarz, 630 South Kingshighway, St. Louis, Secretary.
- American Heart Association, Cleveland, June 12. Dr. Irl C. Rigg, 50 West 50th Street, New York, Executive Secretary.
- American Laryngological Association, Cleveland, June 7-9. Dr. William V. Mullin, 9204 Euclid Avenue, Cleveland, Secretary.
- American Neurological Association, Atlantic City, June 4-6. Dr. Henry Alsop Riley, 117 East 72d Street, New York, Secretary.
- American Ophthalmological Society, Lucerne, in Quebec, Canada, July 9-11. Dr. J. Milton Griscom, 2213 Walnut Street, Philadelphia, Secretary.
- American Orthopedic Association, Rochester, Minn., June 6-9. Dr. Ralph K. Ghormley, Mayo Clinic, Rochester, Minn., Secretary.
- American Physiotherapy Association, Cleveland, June 13-16. Mrs. Bess Scarls, 1430 West 77th Place, Chicago, Secretary.
- American Proctologic Society, Cleveland, June 11-12. Dr. Frank G. Runyon, 1361 Perkiomen Avenue, Reading, Pa., Secretary.
- American Psychiatric Association, New York, May 28-June 2. Dr. William C. Sandy, State Education Building, Harrisburg, Pa., Secretary.
- American Society of Clinical Pathologists, Cleveland, June 8-11. Dr. A. S. Giordano, 531 North Main Street, South Bend, Ind., Secretary.
- American Surgical Association, Toronto, Canada, June 4-6. Dr. Vernon C. David, 59 East Madison Street, Chicago, Secretary.
- American Therapeutic Society, Cleveland, June 8-9. Dr. Oscar B. Hunter, 1835 Eye Street, N. W., Washington, D. C., Secretary.
- American Urological Association, Atlantic City, May 22-24. Dr. Gilbert J. Thomas, 1009 Nicollet Avenue, Minneapolis, Secretary.
- Arizona State Medical Association, Prescott, June 7-9. Dr. D. F. Harbridge, 822 Professional Building, Phoenix, Secretary.
- Association for the Study of Allergy, Cleveland, June 11-12. Dr. Warren T. Vaughan, 808 Professional Building, Richmond, Va., Secretary.
- Association for the Study of Internal Secretions, Cleveland, June 11-13. Dr. F. M. Pottenger, Pottenger Sanatorium, Monrovia, Calif., Secretary.
- Connecticut State Medical Society, Bridgeport, May 23-24. Dr. Charles W. Comfort, Jr., 27 Elm Street, New Haven, Secretary.
- Maine Medical Association, Bangor, May 28-29. Miss Rebekah Gardner, 22 Arsenal Street, Portland, Secretary.
- Massachusetts Medical Society, Worcester, June 4-6. Dr. Walter I. Burrage, 182 Walnut Street, Brookline, Secretary.
- Medical Library Association, Baltimore, May 21-23. Miss Marjorie J. Darrach, 645 Mullett Street, Detroit, Secretary.
- Medical Women's National Association, Cleveland, June 10-12. Dr. Elizabeth Kittredge, 3906 McKinley Street, Washington, D. C., Secretary.
- Montana Medical Association of Helena, July 11-12. Dr. E. G. Balsam, Box 88, Billings, Secretary.
- Nebraska State Medical Association, Lincoln, May 22-24. Dr. R. B. Adams, Center McKinley Building, Lincoln, Secretary.
- New Jersey Medical Society of Atlantic City, June 5-8. Dr. J. B. Morrison, 66 Milford Avenue, Newark, Secretary.
- North Dakota State Medical Association, Fargo, May 28-29. Dr. Albert W. Skelsey, 20½ Broadway, Fargo, Secretary.
- North Pacific Pediatric Society, Vancouver, B. C., June 18. Dr. R. H. Somers, 1305 Fourth Avenue, Seattle, Secretary.
- Oklahoma State Medical Association, Tulsa, May 21-23. Dr. L. S. Willour, Ainsworth Building, McAlester, Secretary.
- Pacific Northwest Medical Association, Salt Lake City, June 21-23. Dr. C. W. Countryman, 407 Riverside Avenue, Spokane, Wash., Secretary.
- Rhode Island Medical Society, Providence, June 7. Dr. J. W. Leech, 167 Angell Street, Providence, Secretary.
- Utah State Medical Association, Salt Lake City, June 21-23. Dr. Leland R. Cowan, 305 Medical Arts Building, Salt Lake City, Secretary.

Current Medical Literature

AMERICAN

The Association library lends periodicals to Fellows of the Association and to individual subscribers to THE JOURNAL in continental United States and Canada for a period of three days. Periodicals are available from 1925 to date. Requests for issues of earlier date cannot be filled. Requests should be accompanied by stamps to cover postage (6 cents if one and 12 cents if two periodicals are requested). Periodicals published by the American Medical Association are not available for lending but may be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

Titles marked with an asterisk (*) are abstracted below.

American Journal of Medical Sciences, Philadelphia

Heart Disease in Pregnancy—The incidence of cardiac murmurs in pregnant women in Lamb's series was 61 per cent. Of these 27 per cent had organic heart disease, while 34 per cent had only functional murmurs and no detectable lesion. None of these patients showed the slightest evidence of cardiac strain during pregnancy and follow-up studies show that nearly all of these functional murmurs disappeared after pregnancy. Rheumatic heart disease causes about 90 per cent of the heart lesions in pregnant women. The most frequently observed lesion is mitral stenosis with or without insufficiency. A third of the cases of mitral stenosis decompensated while no case of uncomplicated mitral insufficiency decompensated demonstrating the importance of differentiating between these two lesions. The functional classification of pregnant cardiac patients has been considered and it was noted that five patients out of those with and without organic heart disease who were able and unable to carry on ordinary physical activity without discomfort decompensated which is at variance with the work of Pardee, who asserts that these patients have an excellent prognosis. Other factors, in the author's opinion must be considered in addition to the functional classification such as the age of the patient, the family environment, the duration of the heart disease and the extent of valvular damage. Most of the patients who decompensated did so before the onset of labor and there was no relationship demonstrated between the month of pregnancy and the onset of decompensation. The mortality was 75 per cent, which falls within the mortality range of from 5 to 10 per cent as reported by reliable observers. Two of these deaths were probably preventable. Consideration of the mortality of the patients having prenatal care and those who did not shows a death rate of 22 per cent in the former and 20 per cent in the latter. The limited follow up showed that 56 per cent were not worse following pregnancy while 43 per cent were. The need for further follow-up study to determine what happens to the cardiac mother and her child after the lying in period is obvious.

Sedimentation Tests—Greisheimer and her associates studied the blood sedimentation in ninety-nine men and 102 women, selected without regard to age or health from university students and ambulatory patients to establish the interrelationships between the Linzenmeier, Cutler and Westergren sedimentation methods. The average sedimentation in one hour for normal subjects appears to be reasonably concordant for the three methods despite the wide differences in the width of the tube, anticoagulant concentration and length of the fluid column, although the differences between the means for the three methods are significant statistically. The average sedimentation at one hour for women is approximately double that for men. The concordance between the results by each pair of methods for the individual patients has been subjected to analysis by preparing the correlation tables. The regression lines for predicting the most likely value to be expected by any one test when that by another is known, proved to be of three distinct types. There is a rectilinear relationship between the Cutler index and the Linzenmeier index. The regressions between the Westergren index and the Cutler or the Linzenmeier index appear to be somewhat like saturation curves. However they had to be fitted by a systematic scheme of free-hand graduations for lack of a suitable type of mathematical equation. The relationships between the various indexes and Linzenmeier time values may be suitably portrayed by section of hyperbolas. The dispersals of individual cases about the lines of average relationship although not studied in detail, are clearly greater than those ascribable to errors inherent in the techniques. The conclusion is clear that sedimentation measures for human blood are, in part, specific for the technique employed. Standardization of a generally acceptable method for blood sedimentation would prove most advantageous for clinical work.

Tularemia Treated by a Specific Antiserum—Foshay states that an initial trial has shown that the goat can be made to yield a potent antitularenses serum, which is effective in treating tularemia in man. The intravenous administration of this serum produced a marked and prompt amelioration of symptoms in fourteen out of fifteen tularemia patients and caused a shortening of the duration of adenopathy, the period of disability and the total duration of disease. One patient, who was received in a dying condition with extensive involvement of the lungs, liver and spleen was not improved. The antiserum has a specific desensitizing action. There is evidence to show that its beneficial effects in man are intimately associated with this property and perhaps dependent on it. The maximal amount of serum given to any one patient was 26 cc. Within twenty-four hours after the administration of the serum there is usually complete relief from headache and a marked diminution in intensity of general malaise, arthralgias and myalgias. The author states that the method of production of the serum and the results of its experimental use in laboratory animals will be reported elsewhere.

Tonometry in Pernicious Anemia—Suher observed that intra-ocular tension is markedly lowered in nearly every case of primary anemia, but particularly in agranulocytosis and pernicious anemias. Apparently in aplastic anemia and leukemia the intra-ocular tension is also reduced. Only with the return of a nearly normal or definitely improved blood picture does the intra-ocular tension return to nearly normal or normal. The decreased intra-ocular tension in the anemias seemingly does not predispose the eye to any intra-ocular complications though the anemia may be of a severe character or of long

duration Prolonged decreased intra-ocular tension alone does not cause any marked functional complications. If any ocular lesion accompanies the anemia, the former assumes greater seriousness and proves rather obstinate. The decreased intra-ocular tension seems to bear a closer relationship to the hemoglobin and the erythrocyte count than to the color index and the leukocyte count. A marked drop in the hemoglobin and in the number of erythrocytes and leukocytes is accompanied by a drop in the intra-ocular tension. A rise in these humal constituents is accompanied by a rise in tension. Not so infrequently does a reverse occur. A variation in the blood picture during the course of the anemia is likely to be accompanied by a variation in the intra-ocular tension. In the author's twenty-five cases there was no case of hyperpiesis associated with the anemia. No intra-ocular lesion was engendered during the course of the anemia. No marked fundus vessel alteration was noticed in any case. In all cases the fundus had a more or less waxy hue.

New Pyelographic Technic—Wesson has the patient enter the hospital the night before examination. Water is forced during his waking hours and he must have at least one liter before going to sleep and another in the morning before cystoscopy. Barbitol, 0.3 Gm., is given on retiring and again at 7 a. m. At 7:30 the patient is catheterized and a sterile specimen sent to the laboratory for culture, and through the catheter an ounce of a local anesthetic (4 per cent procaine hydrochloride, 1,000 nupercaine or 2 per cent metycaïne) is injected. At 8 o'clock the patient is given one-fourth gram (0.016 Gm.) of morphine, hypodermically. Cystoscopy is then done with little disturbance to the dozing patient. Specimens are collected for microscopic examination and cultures and then phenolsulphonphthalein is injected intravenously; the appearance time noted and collections made over two fifteen minute periods. An ampule of neo-iopax is injected intravenously and a flat plate measuring 14 by 17 inches is made immediately. The table is then placed in the Trendelenburg position and the catheters are plugged and five minutes later a second picture (stereoscopic) is made and the plate developed. If there is a satisfactory filling, the other stereoscopic picture is taken. When the pelvic outline is not sharp, 135 per cent sodium iodide is injected through the catheters by means of two 25 cc. burets attached to a ring stand so that there cannot be more than 18 inches of pressure. The fourth picture is a vertical one with the catheters removed at the instant the picture is taken. The patient is then sent to his room, placed in a hot bath for fifteen or twenty minutes to relieve or prevent kidney colic, and usually goes home in the afternoon. In both the intravenous injection with the catheters plugged and the combination of intravenous and retrograde pyelograms, the author has obtained well marked kidney outlines and pelvic filling on each side.

Bardenheuer-Picque Resection in Osteomyelitis of Sacro-Iliac Joint—Kulowski reports four cases of osteomyelitis that were treated by the Bardenheuer-Picque technic as it was developed in his clinic. No other instances of pyogenic osteomyelitis of the sacro-iliac joints so treated have been mentioned in the literature. The procedure lends itself admirably to the principles systematized by Orr in the treatment of osteomyelitis: adequate drainage of the bony focus, adequate rest and protection of the parts until healing has taken place, and the prevention of secondary infection by the elimination of frequent meddlesome dressings, which such enforced plaster cast immobilization minimizes. The latter will bear special emphasis. The prevention of secondary infection is an axiom in surgical tuberculosis. Picque was adamant in its observation. It is no less important in the treatment of osteomyelitis.

Acromioclavicular Dislocation—Roberts describes an approach to the outer end of the clavicle and the coracoid process that gives full exposure to all the essential regions and respects anatomic structures, thus minimizing bleeding and facilitating wound closure. The incision is a modification of the upper angle of the approach of Henry to the humerus and shoulder joint. 1 A curved skin incision is made starting at the acromioclavicular joint and running medially along the outer curve of the clavicle and then turning down to pass just inside the tip of the coracoid process. The downward arm of the incision follows the sulcus between the deltoid and the pectoralis major. The total incision describes a little less than a semicircle. 2 The skin flap is retracted back, exposing the deltoid muscle. The acromioclavicular joint can then be exposed by a short incision through the upper part of its capsule. The deltoid is separated from the clavicle by detaching a small strip of bone containing the muscle insertion or by dividing its semitendinous insertion near the clavicle, leaving enough tissue attached to the bone to which to resuture the muscle. 3 The

inner border of the deltoid is separated from the fatty tissue that lies between it and the pectoralis and then the muscle is retracted outward and downward, exposing the coracoid process. The blood vessels entering the muscle from beneath must be cut and sutured, but this is the only point at which any bleeding is encountered. The acromioclavicular joint, the outer portion of the clavicle and the coracoid process are thus made accessible for any repair indicated. After repair of the injured ligaments is completed, the deltoid is reattached to the clavicle by passing two or three sutures through the muscle and round the clavicle. These should be placed before the ruptured ligaments are repaired and while the end of the clavicle is still loose and may be lifted up to allow the suture needle to pass close to the under surface of the bone without endangering any blood vessels. When these sutures are tightened, the slip of bone containing the deltoid attachment is lashed back into place, where it unites firmly.

Tuberculosis Among Children of Tuberculous Parents

—The 592 children of parents with open pulmonary tuberculosis in 128 white and eight Negro families in the industrial population of Cambridge, Mass. have been followed by Everts and her associates into adult life and a study has been made through questionnaires checked by official records of the tuberculosis rate among them. Attention is given chiefly to the 554 children who were born before or while the parent's case was known to be active and were therefore thoroughly exposed to the disease. Tuberculosis mortality, from 15 to 39 years was at least between two and three times as high among offspring of white tuberculous parents as in the general white industrial population. The maximal number of cases among men occurred ten years earlier than in the general industrial population, while for women this maximum is approximately at the same age in the two groups. The age group from 5 to 14 years was as free from tuberculosis in one group as in the other. Children in families of English and American stock were found to be slightly less subject to tuberculosis than those of Irish or Nova Scotian stock. Bad homes and double parental exposure seemed to be important in causing tuberculosis among these children. Removal of the ill parent from the home carelessness in sputum disposal and whether exposure was to father or mother seemed to be of no importance. Many of the children who developed tuberculosis in adult life were first exposed in late childhood. Often many years elapsed between the time of known exposure and the development of disease. About two thirds of the families of white tuberculous parentage have grown up without, so far any known case of tuberculosis among the children.

Simplified Technic for Blood Sedimentation Indexes

—The modification of Van Antwerp is as follows. Of a sterile 3 per cent solution of sodium citrate 0.2 cc is drawn from a serum bottle and the syringe is filled to the 2 cc mark with blood removed from a vein. A bubble of air is then drawn through the needle into the syringe and the blood and citrate

are mixed. The bubble is expelled, the needle is removed and replaced by a cap and the capped syringe is placed in a test tube rack for observation. The caps were made by breaking the needle from a discarded hypodermic needle and filling the perforation with paraffin. A 24 gage, 1 inch needle seems best suited for use in the test. Readings are limited to a single one taken at the end of one hour. The advantages of this simplified technic are the following. The elimination of one or more steps in the determination of the index materially reduces the time necessary for the procedure. The small amount of blood necessary (18 cc) allows the use of a small hypodermic needle, which causes a minimum of discomfort to the patient and facilitates entrance to the small veins of children. A minimum of equipment is necessary and, once the syringe (which can be put to other uses in the private office) is acquired, the apparatus can be found in any physician's office, with the exception of the sterile citrate solution. The sterilization necessarily preparatory to the test is no more than is required for ordinary venipuncture. The index is determined by a single reading at the end of an hour and the apparatus requires no attention during this time.

Use of Glycine in Treatment of Myasthenia Gravis—

Schmitt presents two cases of myasthenia gravis which showed definite clinical improvement on a combination treatment of ephedrine sulphate and glycine. The administration of glycine was accompanied by an increase in the elimination of creatinine and preformed creatinine nitrogen. The maximum output of creatinine nitrogen occurred on the twelfth day in one case and on the twenty-second day in the other one. The average excretion during the test period was 0.628 and 0.74 Gm, respectively. There was a definite drop in the excretion of the urinary creatine nitrogen from a value in one case of 0.312 Gm (before the test) to a daily average excretion of 0.066 Gm for the test period of thirteen days. In the other case this decrease was from 0.123 Gm before the test period to a daily average excretion of 0.045 Gm a day (period of twenty-three days). The ratio of the creatine nitrogen to preformed creatinine nitrogen in both cases fell under glycine administration from a ratio of 1.07:1 to an average ratio of 0.106:1, and from one of 0.2:1 to one of 0.06:1, respectively. A dosage of 15 Gm twice daily of glycine is an effective and probably the optimal dosage. Ephedrine sulphate seems to augment the efficacy of the glycine. In the author's experience a dosage of three-eighths grain (0.024 Gm) twice daily given about twenty minutes after the dose of glycine is the optimal dosage. This dosage seems superior to a small one of three-sixteenths grain (0.012 Gm).

Pneumococcal Meningitis Recovery with Felton's

Serum—Reveno and McLaughlin successfully treated a patient having pneumococcal meningitis (probable portal of entry the paranasal sinuses) with the infecting organism pneumococcus type I and II by intravenous intraspinal and intracisternal instillations of 120,000 units of Felton's antipneumococcus serum. Recovery set in after seven days of treatment and was evidenced not only by clinical improvement but by a reappearance of sugar in the cerebrospinal fluid a lowering of its cell count and a drop in the proportion of nonfilament cells in the

blood smear The nonfilament decrease was relied on as a gage of the activity of the infection As long as this figure remained between 8 and 16 it was felt that the infectious process was under adequate control As a residue of the disease, the patient had a right facial and a right abducens paralysis The former developed on the fourth day and the latter on the day after admission to the hospital The facial involvement cleared rapidly but the sixth nerve paralysis took fully two months for recovery

Treatment of Postarsphenamine Dermatitis—Shaffer points out that the staff of the City Hospital in Detroit has employed dextrose occasionally in the treatment of postarsphenamine dermatitis for the last five years It is difficult to evaluate the results, because the number of patients treated was not large and because cases of arsenical dermatitis vary greatly in the severity of manifestations and in the length of hospitalization Results from the use of dextrose were encouraging and at times almost miraculous so that such treatment has been continued The use of dextrose in dilute solutions (from 2 to 10 per cent) as a diluent for arsphenamine has been recommended by several investigators to prevent arsphenamine reaction, as well as its use by mouth preceding the injection Arsenic combines with dextrose to form glucosides which are less toxic, which have a tendency to remain in the blood stream over a longer period and which are excreted more rapidly The author proposes to treat any new patient (nondiabetic) having accessible veins with 1 Gm of sodium thiosulphate and 50 cc of a 50 per cent solution of dextrose injected intravenously daily for from three to five days The administration of the dextrose should be followed in one-half hour by 5 units of insulin Patients in whom venipuncture is difficult or impossible should be treated with liver extract by intramuscular injection or with calcium gluconate according to the saturation technic of Karrenberg The usual supportive and local measures of treatment were employed

Epithelioma of the Ear—Lehmann emphasizes the fact that radiation in the treatment of epithelioma of the cartilage of the ear cannot be standardized to fit every case A small basal cell epithelioma on the skin, not attached to the cartilage, can be satisfactorily treated with beta rays shielded close round the epithelioma If infection complicates the epithelioma the success is rendered more uncertain nevertheless it would be best to use gamma radiation (whether the lesion is of basal cell type or not) If the cartilage is already invaded irradiation is futile If the epithelioma is not a basal cell but a prickle cell type, it will require a heavy dose of radiation Beta rays should not be selected for it because of the danger of irreparably damaging the perichondrium and therefore gamma rays should be used The effect of previous treatment has to be taken into consideration For instance in a recurrence of an epithelioma that has been treated before with soft radiation (roentgen rays or beta rays of radium) one would consider how much the perichondrium is damaged If there is no marked atrophy of the skin, one could well apply further radiation with gamma rays If there is evidence that the perichondrium is broken, the efficacy of further radium treatment is doubtful

 Fifty Second Report of Progress in Orthopedic Surgery J G Kuhns, E F Cave S M Roberts and J S Barr Boston J A Freiberg Cincinnati J E Milgram New York R I Stirling Edinburgh Scotland and P D Wilson, Boston—p 417

Hyperinsulinemia Secondary to Adenoma of Pancreas—Ross and Tomach present the history and course of a case of hyperinsulinemia with hypoglycemia secondary to a tumor involving the islands of Langerhans The case differs from the cases reported previously in that the onset was apparently abrupt with complete loss of consciousness and evidence of external injury that caused the symptoms to be attributed to cerebral edema or concussion During each of his seizures of hypoglycemia, the patient presented the semi Babinski or extensor response described by Hart and Bond as a diagnostic aid in differentiating between insulin shock and diabetic coma The complete absence of hypoglycemic seizures together with the clinical and laboratory evidence of the establishment of a normal carbohydrate metabolism immediately after the excision of the small pancreatic nodule is, the authors believe, adequate proof that this man's symptoms were due to the excessive production of insulin by the tissue of the tumor The data presented, together with the clinical and experimental evidence cited in the cases reported previously, suggest again that tumors arising from glandular tissue may in some instances retain the function of the organ or tissue from which they arose At the present time, exploration with removal of the adenoma, if demonstrable offers the best chance of clinical cure

Chromatophore Tumors of Mammary Gland—Hertzler has observed that the malignant tumors of the mammary gland which possess a pseudocapsule, in whole or in part, always terminate fatally within a year or two, no matter how soon after the discovery of the tumor operation is performed, or what the extent of the operation is or whether or not there are palpable metastases These tumors occur in women at the menopause or beyond that period There is a group of tumors which begin within the acini and in which the cells are loosely joined and diffusely scattered Some of these appear as though they might have arisen from the subepithelial cells, but instead of growing away from the lumen of the acini they grow into it At any rate many of these tumors are globular, though they do not develop a pseudocapsule, and their course is usually malignant Intracanalicular fibro-adenomas may give rise to malignant tumors which spring from the subepithelial layer They run a course parallel with that of the chromatophore tumors in the skin

Cranial Osteomas Produced by Meningeal Fibroblastomas—Echlin attempts to explain the nature of osteomas of the external surface of the cranium The material on which the study is based was collected from 2,000 cases of tumors of the bone and 1,000 cases listed under tumors of the head and skull, which included 350 cases of tumor of the brain All the osteomas of the external surface of the cranium or hyperostoses caused by meningeal fibroblastomas were verified by microscopic examination Osteomas may be either spongy or eburnated and they arise from preosseous tissue on the cranial surface, as a rule, early in life They grow slowly and most frequently take origin from the frontal bones They usually arise in the growing bone The spongy type of osteoma

usually causes an absorption or spongy transformation of the outer table of the cranium and becomes continuous with the diploe. As a result of this process, the inner table of the skull in the region of the tumor may become slightly depressed and thickened. A layer of bone is sometimes laid down on the surface of the tumor. Microscopically, this bone is young in type and is being actively formed from preosseous tissue. This type of osteoma has often been described as arising from the diploe. The fundamental pattern of ossification for osteomas of the cranium, characterized by subperiosteal growth with accompanying spongy transformation of underlying bone and the frequent deposit of a subperiosteal shell of new bone, is also typical for similar new growths arising in other membranous bones. Osteomas of the cranial surface rarely arise in adults. Osteomas of membranous bones are a distinct entity from exostoses (osteochondromas) in cartilaginous bones. Osteomas usually arise in youth and hyperostoses in the fourth decade of life. Compression of the brain a common feature of hyperostoses, is rarely caused by osteomas unless some complicating factor is present. Hyperostoses are more frequently tender than osteomas and unlike osteomas are sometimes compressible. The roentgenographic differences between these two bony growths are distinctive. In hyperostosis ossification adjacent to the tables of the skull occurs in parallel strips under the periosteum and endosteum when these tissues are minutely elevated by the meningeal tumor in its growth. When these tissues become more completely stripped from their attachments new bony trabeculae are laid down at right angles to the cranium. In the region of a meningeal fibrosarcoma a small amount of thickening of the skull may result purely from hypervascularization, but the production of a hyperostosis of any appreciable size is apparently always due to the infiltration of the skull by the cells of the meningeal tumor. Osteomas that cause severe pressure on the brain usually arise either about the paranasal sinuses or the orbit or from the inner surface of the skull and not in the periosteal region on the cranial surface.

Inhibition of Bacteriophage Action by Bacterial Extracts—Levine and Frisch present experiments that demonstrate specific inhibition of bacteriophage by soluble products of bacteria. The inhibition proceeds more rapidly when the bacteriophage and bacterial extracts are incubated at 37 C than at icebox temperature. The specificity of the reaction in the instances studied is probably connected with the presence of specific soluble carbohydrates. A reaction is available for the study of the chemistry of bacillary antigens in terms of bacteriophage.

Variations in Blood Following Dextrose Ingestion—Bruger and Mirsky point out that the ingestion of 100 Gm of dextrose by fasting subjects produced the following effects:
1 The urea nitrogen content of the blood may rise or (and) fall or remain unchanged. A gradual fall in the urea nitrogen (from 1 to 7 mg per hundred cubic centimeters) was observed in twenty-two out of forty-five cases. A definite decrease (3 mg or more per hundred cubic centimeters) occurred more often in subjects with diminished carbohydrate tolerance than

in those with normal tolerance 2 The total nonprotein nitrogen of the blood may rise or (and) fall or show no marked change In many cases the variations in the total nonprotein nitrogen were due mainly to changes in the urea nitrogen fraction Irregular changes were noted in some instances in the sum total of the nonprotein nitrogenous substances in the blood other than urea 3 There was a distinct reciprocal relationship between the whole blood and plasma chlorides and the dextrose concentration in the blood in many instances, though this was not observed in all the cases studied There was no apparent relationship between the degree of diuretic response to dextrose and the variations in the constituents investigated Diuresis following dextrose ingestion occurred more frequently and was more marked in subjects with normal carbohydrate tolerance than in those exhibiting a diminished tolerance for sugar The hypothesis is suggested that these fluctuations represent an effort by the body to maintain a constant osmotic pressure of the blood The compensatory response of urea, total nonprotein nitrogen and chloride to a rise of dextrose in the blood is not a uniform reciprocal relation The varied increase or decrease of these substances suggests that the total osmotic pressure is adjusted according to the physiologic reserve prevailing in the body at a given moment

Complement Fixation Test for Amebiasis—Tsuchiya offers a new culture medium (S C medium) for *Endamoeba histolytica* which consists of 10 Gm of peptone 3 Gm of meat extract, and 5 Gm of sodium chloride in 1 liter of distilled water adjusted to pH 7 and autoclaved at 15 pounds pressure for thirty minutes The pH of the medium within the range of 6.8 and 7.4 also answers the purpose, though the optimum is found to be 7 When complement fixation tests were carried out with an antigen prepared from cultures of amebas grown in the foregoing medium the following results were obtained Of 153 persons examined, 135 known to be free of amebic infection were found to give a negative serologic test Of the remaining eighteen, eight were known carriers of *Endamoeba histolytica* and gave positive serologic reactions Six were diagnosed as having clinical amebic dysentery and exhibited positive serologic reactions except in one case in which repeated trials failed to show any capacity to fix complement There were four cases of ulcerative colitis that showed positive serologic tests but no amebas were detected in the examinations of the stools Thus, a negative serologic test appears to be quite significant and valuable for eliminating the possibility of amebiasis in a given person A positive serologic test also seems to be quite specific in demonstrating the presence of *Endamoeba histolytica*

Wassermann and Kahn Reactions on Spinal Fluid in Dementia Paralytica—Sackett and Eselius observed that the Wassermann reaction (Craig) on spinal fluid gives a higher proportion of positive reactions in treated and untreated cases of dementia paralytica than the standard Kahn or the modified Kahn employing the serum antigen titer The agreement between the three reactions is relatively high in nondementia paralytica and untreated cases, but falls off rather sharply in treated cases The modified Kahn reaction employing the serum antigen titer gave a higher proportion of positive reactions in treated and untreated cases of dementia paralytica than the standard Kahn test One false positive reaction was observed among forty-eight nondementia paralytica patients with the modified Kahn reaction, indicating a possibility of error if this test is used exclusively The authors method for removing the excess ammonium sulphate from the precipitated globulin differs from the method of Kurtz and Larkum in that, after the globulin has been thrown down by centrifugating, the supernatant fluid is carefully pipetted off and the tube is placed in an inverted position on some filter paper and allowed to drain for half an hour Then the inner sides of the tube are carefully dried by means of a cotton applicator, great care being taken not to disturb the precipitated globulin The globulin is then ready to be redissolved and the regular Kahn technic continued except that the antigen serum titer can be used In their study they did not concentrate the globulin dilution but followed the routine Kahn procedure for spinal fluid In removing the supernatant fluid they found that if great care was used it could be poured instead of pipetted off without affecting the end-result of the test

Experimental Study of Mapharsen as an Antisymphilitic Agent—Tatum and Cooper point out that mapharsen (meta amino parahydroxy phenyl arsenic oxide) is a pure chemical preparation, the purity of which can be determined The arsphenamines on the other hand, are chemical mixtures, and consequently the toxicity and therapeutic values may vary with each lot Mapharsen becomes slowly less toxic on oxidation whereas the arsphenamines become quickly much more toxic Nitritoid reactions should be entirely absent with mapharsen For therapeutic uses in experimental rabbit syphilis, mapharsen is required in quantities representing only one-fifth to one-thirtieth the amount of arsenical drug that is required with neoarsphenamine The therapeutic index, i. e., the ratio of the maximal tolerated dose to the curative dose, is distinctly greater for mapharsen than for neoarsphenamine in experimental syphilis The administration of mapharsen twice a week in amounts of one-fifth to one-half the maximal tolerated dose, for ten weeks, does not cause any evident intoxication in the animals It does not seem likely that the repeated use of this compound in the clinic should cause any cumulative effects From the practical standpoint, mapharsen can be safely ampuled with sufficient dry sodium carbonate to neutralize the acid and enough sodium chloride to make an isotonic solution when the drug mixture is dissolved in the specified quantity of sterile distilled water The authors are convinced that mapharsen has such advantages over the arsphenamines as to justify its clinical investigation

Prediction of Sex of Fetus—Davis in his attempt to determine the sex of the fetus injected intradermally from 0.2 to 0.3 cc of stock testicular extract. The reactions were labeled as negative (no reaction), one plus (a red area 12 mm in diameter), two plus (red area from 12 to 20 mm in diameter), and three plus (a red area more than 20 mm in diameter). The readings were made in from four to ten minutes after the injection. The reactions disappeared, as a rule, within a few hours. The injections were slightly painful from the stretching of the skin but the patients did not usually object to them. Practically none of the patients reported any residual soreness. A negative reaction indicated a female fetus, the two and three plus reactions showed male children. The records of the one plus reactions were almost equally divided between the males and the females. The 136 cases tested with the stock testicular extract gave poor results therefore more of the extraneous protein was removed from the solution. With the new ampules 534 more cases were tested with moderately good results. There was an accuracy of 82.3 per cent in the 294 male fetuses and 89.6 per cent in the 174 female fetuses. Of the one plus reactions, twenty-nine were male and thirty-seven were female fetuses.

Protein Fever Treatment in Resistant Syphilis—As Nelson reported previously, the technic consists in giving two intravenous injections of combined typhoid vaccine for each fever paroxysm, instead of one. The injections are made from two to three hours apart, and the second dose is given at the height of the fever induced by the first. The doses used are smaller than those that must be given ordinarily. By observing reactions the dosage necessary to produce the desired degree of fever in any case can be estimated accurately. In order to arrive at an idea of the patient's reactivity, for the first few days treatment is given by the single injection method, beginning with a dose of about 50 or 100 million dead typhoid bacilli and doubling the dose each day, depending on the severity of the reaction induced. After a few days of trial in this way the double injections are started, beginning doses of about one-tenth as large as the last single dose being used. The first dose each day should be just large enough to produce a fever of about 99 or 100 F. The second dose should be about the same size as the first, but, if by experience it is found necessary to make it larger, it should be correspondingly increased. This second dose has a peculiar "explosive" effect—it seems to ignite a charge created in the body by the first dose causing the patient's temperature to mount to 107 F or more. As with usual methods, it is necessary to increase the amount of the dosage each day because of the immunity to the vaccine that develops in the body. The author emphasizes the fact that the method is convenient and readily available and can be put to general use early in the course of resistant syphilis, while it is still possible to prevent organic damage to the body from taking place. It has brought about improvement equal to that observed in similar cases treated by malaria.

Patent Interventricular Septum—Of 100 cases of congenital heart disease in elementary school children Muir and Brown observed forty to have a patent interventricular septum as their sole abnormality. A harsh, prolonged, mesocardial systolic murmur of maximal intensity in the third and fourth left interspaces close to the left sternal margin was the principal physical sign. The first intimation of the presence of a cardiac lesion was at the routine school entrance examination in twenty-eight cases. Of the remainder, in only one case was the lesion recognized at birth. In eleven cases the abnormality was discovered during some illness (influenza, measles or pneumonia). The authors' study of these patients seems to indicate that this condition is commoner than is generally recognized. A proper appreciation of the physical signs as described by Roger would lead to the more frequent identification of this defect. In the present series there was no case of heart block or of infective endocarditis. They suggest that a lesion of the interventricular septum alone is not the whole cause of congenital heart block. Permanent cyanosis is not a part of the clinical picture of the malady of Roger. When cyanosis is permanently present it is due to some accompanying structural abnormality. There is no characteristic roentgenologic picture of this defect.

Diabetes Mellitus Associated with Degeneration of Suprarenals—Brookfield and Corbett state that the association of diabetes mellitus with gross pathologic changes in the suprarenals is uncommon. The case of diabetes that they report is of interest because of its unusually high blood sugar values and the enormous doses of insulin required during the course of treatment. There seems to be no explanation for the exceptionally high blood sugar level (1,040 mg per hundred cubic centimeters) before treatment was instituted. Still higher values, amounting to 1,400 and 1,490 mg per hundred cubic

centimeters, respectively, have been reported by Joslin in two fatal cases. The massive doses of insulin required to bring the blood sugar back to the normal level are almost certainly related to the high initial blood sugar value. In the first twenty-four hours of treatment 460 units of insulin was given, for the next three days 240 units daily, and thereafter approximately 160 units daily. On one day, when the dose was reduced to 120 units, the blood sugar again rose to 296 mg per hundred cubic centimeters, indicating that the doses previously given were not unnecessarily large. As there was no rise of temperature until the third day after admission to the hospital, by which time the blood sugar had been reduced to 200 mg per hundred cubic centimeters, neither the high blood sugar nor the necessity for the large doses of insulin can be ascribed with certainty to the presence of infection. At necropsy an advanced degenerative lesion of the suprarenals was discovered.

Reduction of Fractures of Neck of Humerus—Anderson describes a method for the reduction of fractures of the surgical neck of the humerus in which the ordinary methods of reduction have proved unsuccessful, which consists of partial transfixion of the head of the bone by a bone awl passed through a stab incision on the outer aspect of the shoulder. The procedure is carried out under the screen in the roentgen department. It consists of traction of the limb in the adducted position in order to pull the lower fragment down to the level of the upper end, while maintaining this pull adducting the arm across the chest. The adducted or upper fragment is now adducted by depressing the handle of the bone awl. It is then easy to engage the upper end of the lower fragment in the fractured surface of the upper. The arm is slowly brought back to a slightly abducted position, where it is maintained by splints. Once accurate approximation of the two surfaces is obtained there is little tendency for the fragments to slip.

- *Certain Aspects of Metabolic Response to Injury D P Cuthbertson—p 41

Metabolic Response to Injury—Cuthbertson describes the series of metabolic changes that take place on receipt of a wound in two successive phases—the initial phase of depressed vitality or shock and the phase of renewed functional activity and healing. During the phase of depressed vitality that generally results from physical injuries there occurs within the first twenty-four hours a period of relative or absolute anuria of varying duration. Following this early period of diminished urinary secretion the volume of urine and the output of nitrogen rise reaching in the latter a maximal daily loss during the fourth to the eighth days which may even exceed 23 Gm. The maximal secretion of urine generally occurs two days after the maximal output of nitrogen. The reduction in the nitrogen content of the organism may exceed 7 per cent in the first ten to twelve days following a serious injury. The excretion of sulphur and phosphorus rises parallel to that of nitrogen. There is still a slight but continuous loss even after the lapse of one or two months. The sulphur, nitrogen and phosphoric oxide, nitrogen ratios suggest that the material catabolized was probably mainly muscle. During the initial period of depressed function the patient's heat production and body temperature are diminished but during the subsequent phase of enhanced vitality there is an increase in heat production and body temperature. With but few exceptions does the rise in temperature exceed 2 degrees C (3.6 degrees F). The increase in the basal consumption of oxygen is generally from 20 to 25 per cent. Coincident generally with the rise in temperature is a rise in the pulse rate the rate of increment being ten beats to each degree Fahrenheit. The curves of the urinary excretion of nitrogen and the basal consumption of oxygen are generally parallel. There appears to be some relationship between the

extent of the injury and the degree of reaction but there is great variation in individual cases. Observations on the metabolic disturbance in pneumonia indicates that the changes are somewhat similar in kind to those which result from trauma, but less marked. It has been shown that atrophy due to nonuse of the injured limbs is only a minor factor in the production of this great disturbance of metabolism, which is almost certainly of a more general rather than local nature.

Death in Aplastic Anemia After Fifty-Two Blood Transfusions—Knott gives the results of treatment by repeated blood transfusions (fifty-two) of a patient suffering from aplastic anemia following prolonged administration of arsenicals. The results indicate that by this means not only may the patient's blood be sufficiently improved to allow him to resume a fully active life but also the functional activity of the blood-forming tissues may steadily improve so that less frequent transfusions become necessary. The records clearly illustrate the low resistance to infection that these patients possess as long as leukopenia is present and their inability to produce a satisfactory protective leukocytosis. In spite of the general physical improvement, the risk of infection is a constant menace to them. From the observations made in this case it would seem justifiable to hope that if infection can be avoided, maintenance of the hemoglobin and red cell figures at a high level by means of repeated blood transfusions may ultimately result in full restoration of the activity of the blood-forming tissue.

Differentiation of Bacillus Diphtheriae—Dockeray offers a modification of the special tellurite medium described by the Leeds workers which has been found to give equally satisfactory results. Its preparation necessitates no special apparatus filters or suction pumps. Two Erlenmeyer flasks of about 500 cc capacity are taken and 150 cc of 5 per cent agar is put in one. This is sterilized in the autoclave and while still liquid is used to prepare the medium. In the other flask is 150 cc of tryptic digest broth. To the broth from 20 to 30 cc of sterile citrated human blood is added followed by 120 mg of potassium tellurite dissolved in a few cubic centimeters of sterile saline solution. The tellurite-blood-broth mixture is warmed to about 40 C and is then poured into the melted agar which has been allowed to cool to about 70 C. The mixture is heated in a water bath at 75 C for ten minutes and when cooled to from 50 to 55 C, is poured as plates. In testing thirty-five apparently healthy residents (nine adults) of an orphanage eight carriers of typical morphologic diphtheria bacilli were observed who gave the characteristic fermentation reactions six being virulent and two nonvirulent. The six carriers of virulent grave strains would

not have been detected if the special tellurite medium had not been used. All the carriers were negative when Schick tested, and in all the tonsils and adenoids were subsequently removed. With the exception of one, they all gave negative cultures on three occasions after this treatment. The author believes that the detection of six virulent carriers out of thirty-five apparently healthy people demonstrates the usefulness of the special medium for the detection of carriers. The special medium has in some cases proved useful in the diagnosis of cases but it suffers from the disadvantage that growth on it is slow. It makes the isolation of Bacillus diphtheriae from mixed cultures an easy matter.

Anomalous Features of the Dick Reaction—McGibbon observed that about one fourth of the cases in a series of 160 patients suffering from scarlet fever appeared to be Dick negative in the acute stage of the disease. Throughout the illness there was a progressive decrease in the number of positives and in the intensity of the reactions, till in the second week two thirds and in the fourth week nine tenths of the total cases were negative. Almost 90 per cent of the original positives showed this characteristic loss of the Dick-positive state. It would appear that this change occurs less readily in young children. Fluctuations in the reaction during the course of the illness are uncommon if indeed they occur at all. Of eleven cases that failed to show the foregoing change, two relapsed. In the other 149 cases no relapses occurred. Pseudoreactions are uncommon. The author suggests that the use of heated filtrate may be unsatisfactory and that the mechanism of these reactions requires further study. He discusses some of the anomalous features of the Dick reaction and believes that these difficulties have been exaggerated and that they do not in themselves form sufficient grounds for concluding that the test is fallacious. On the evidence at present available, one must continue to regard scarlet fever as a specific toxemia. The allergic conception of the disease is less convincing.

Abortive Treatment of Gonorrhea—For each treatment Janet prepares a fresh solution of 1 Gm. of mild silver protein (argyrol) in 5 cc. of cold distilled water, which is completed in fifteen minutes. With a sterilized urethral syringe, from 2 to 5 cc. of the solution is slowly injected into the urethra. The solution is kept in the urethra for five minutes and the patient should not urinate for a number of hours after treatment. The patient should drink very little during meals but may drink in the evening after having urinated and early in the morning after having been at stool. Six injections of the 20 per cent solution of mild silver protein are given to the patient at the rate of two a day. In successfully treated cases no gonococci are observed in the morning secretion by the second day. If any are found the abortive treatment has no value. After three days of treatment the patient is allowed to rest for forty-eight hours and then another injection is given. Before pronouncing the patient cured it is advisable to give him three glasses of beer before retiring. If after two days there is no discharge of gonococci the patient may be pronounced cured.

Muscular Syphilis—Favre and his associates studied two patients affected by syphilis resulting in multiple muscular manifestations and an identical clinical syndrome. The lower extremities became fixed in a malposition as a result of changes in the soft parts, no other explanation being possible. In the first case neither clinical examination nor an incomplete necropsy revealed any lesions of the nervous system. In the other case the necropsy revealed distinct muscular lesions which on histologic study were found to be of syphilitic origin. The author points out as histologic evidence of myositis the extensive muscular involvement, the generalization of vascular lesions and the development of adipose tissue. These lesions have all the characteristics which the author has often observed in syphilitic interstitial myositis. Syphilis is capable of creating complex interstitial alterations in the muscles, which end in the disappearance of the contractile element and in the production of substitutive sclerosis which, in these cases as in others, cause retraction.

- Variations of Cholesteroemia in Acute Infections V. de Lavergne and P. Kissel —p 393
 Gold Salts in Oil Suspension in Treatment of Pulmonary Tuberculosis H. Mollard —p 395

Gold Salts in Treatment of Pulmonary Tuberculosis—Mollard states that results obtained with gold salts in oil suspension are more durable than those obtained with gold salts in aqueous solution. In twenty-three out of a hundred cases he obtained satisfactory immediate results, practical clinical cures with roentgenologic disappearance of lesions, suppression of bacilli and secretory symptoms and general improvement of the patients' condition. Late results of treatment with suspension of gold salts in oil showed that eight out of ten evinced an improvement at the end of two years and the author believes that this kind of treatment gives better assurance against recurrences. The most lasting ameliorations have been shown by patients suffering from syphilis, psoriasis or tuberculosis. In patients in whom the immediate action of the gold salts is not striking the number of late improvements is larger than in patients treated by aqueous solutions of gold salts. Twelve out of thirty-eight tuberculous patients showed remarkable late improvements. The oil suspension is slowly eliminated; it thus permits continued improvement after a partial success at the end of treatment or if the early results have not been encouraging. The only inconvenience of the oil suspension treatment is the necessity of long intervals between the series. The patient is exposed to sensitization symptoms if treatment is begun too suddenly, but the accidents of late solubility do not

seem to exist when there are sufficient intervals between treatments. None of the author's patients have presented any serious symptoms.

Action of 3.5 Diiodotyrosine on Hyperthyroidism—Delcourt-Bernard found that from the physiopathologic point of view diiodotyrosine exerts a beneficial effect on the increased respiratory exchange in the course of hyperthyroidism, whatever the clinical form of the disease may be. Of twelve cases observed by the author, eight presented a lowering and four an elevation of metabolism. The mechanism of the action of compound solution of iodine differs from that of 3.5 diiodotyrosine in that, when the former lowers the metabolism, it seems to act more on aeration than on the consumption of oxygen. When it determines an elevation of the rate of exchange it acts more on the consumption of oxygen than on aeration. Diiodotyrosine, on the other hand, has more of a tendency to lower the consumption of oxygen when it lowers the exchange and to act equally on the two factors when it raises the metabolism. The most important and most frequent increases in the weight of the subjects treated are to the credit of compound solution of iodine. No differences were observed in the action of these two substances on the pulse or on other symptoms of hyperthyroidism. Except for the equivalence of doses the author does not grant to diiodotyrosine the peculiar value that certain German authors have attributed to it and cannot compare it, as many Americans do, to a solution of inorganic iodine acting only on account of the iodine that it contains. From the therapeutic point of view, diiodotyrosine is easily absorbed and well tolerated in the prescribed doses of 0.1, 0.2 and 0.3 Gm. daily. Without possessing the efficacy or the ease of administration of compound solution of iodine, diiodotyrosine may nevertheless be of service in replacing compound solution of iodine or in obtaining a gastric tolerance momentarily diminished with regard to the latter or in being associated with compound solution of iodine after having acted previously by itself. The fact that in certain cases it may determine an elevation of the respiratory exchange with acceleration of the pulse demands a close supervision of cases treated with it.

 Artificial Nutrition E. Briss —p 302
 Traumatic Diseases of Vertebrae P. Rostock —p 313

Treatment of Seminoma—Blümel states that tumors of the testicle are extremely rare. Of 40,000 admissions of male patients to the surgical clinic of the University of Göttingen in twenty years, only 32 presented tumors of the testicle. Seminoma is the most frequent of the testicular tumors. More than two thirds of the thirty-two mentioned belonged to this type. Of twenty-two patients, nine came to the clinic in the state of metastases. Testicular tumors metastasize usually by way of lymphatics to iliac lymph nodes and later to those about the abdominal aorta but seldom involve the inguinal nodes. About the same time metastases can be found in the mediastinum along the thoracic duct. In advanced stages metastases are present in the supraclavicular and axillary fossae. Metastases penetrate the blood vessels relatively early and give rise to liver and lung metastases more rarely to skin metastases. According to Zondek the urine of patients with testicular tumors frequently contains an increased amount

of prolan A, and in some of prolan B as well. It is not of a specific diagnostic value, since it may be present in other testicular diseases, as well as in certain tumors of the brain and the hypophysis. The finding of increased excretion of prolan A is suggestive but not diagnostic of a seminoma; the presence of prolan B is suggestive of the presence of a seminoma or a teratoma. In the author's three cases the metastases were effective in maintaining the increased excretion in the urine of prolan B after the removal of the primary tumor. The primary tumor because of easy approach is always to be removed. The removal of the regional lymph nodes is not advised because of the high mortality attending it. It is, however, important to irradiate the iliac and aortic lymph nodes on the side of the primary tumor even when clinically demonstrable metastases are not present. The irradiation should be repeated if the urine shows an increased excretion of prolan. The author warns against relying too much on the particular roentgen sensitivity of seminoma cells commented on by many authors as this may lead to insufficient dosage and recurrence. From 10 to 15 roentgens a minute is considered the proper dose by the author. Because of more general reactions, fractional doses are advised for extensive metastases.

*Mechanism of Reorption of Percutaneously Administered Esters of Salicylic Acid H. Gehlen and A. Blankenstein—p. 320

Tubercle Bacilli in Circulating Blood—Kollé and Küster show that many leading investigators have failed to corroborate Loewenstein's assertion that tubercle bacilli occur in the circulating blood of from 30 to 40 per cent of patients with various forms of tuberculosis, including lupus. The assertions that in a high percentage of cases of schizophrénia chorea, multiple sclerosis and rheumatic diseases the blood contains tubercle bacilli and that these have an etiologic relation to the diseases have likewise not been corroborated. At any rate, of the many investigators who duplicated Loewenstein's test, none obtained the high percentages reported by him. Particularly in cases of rheumatic polyarthritis the demonstration of tubercle bacilli has been successful in so few cases that at the most it could be considered accidental. The same can be said about schizophrénia and multiple sclerosis. Loewenstein's objection that the technic and the culture mediums have not been perfect and that this explains the negative results of other bacteriologists is untenable in view of the fact that some of those who employed this method studied it in his own laboratory. The author deplors the confusion that has been brought into medical circles by Loewenstein's reports. He points out that it was known long before Loewenstein that tubercle bacilli occur in the blood (which, however, is not a multiplying but only a transporting medium) and that they are demonstrable by the culture method or the animal experiment, for tuberculosis even if localized in a tissue is not a purely local disorder. On the other hand, the assertion that tuberculosis begins with a bacteremia that is with a primary multiplication of tubercle bacilli in the blood stream, is unfounded.

Subarachnoid Hemorrhages—Krohn reports two cases of subarachnoid hemorrhages resulting from aneurysmal cerebral vessels. The symptomatology was characterized by manifestations of central and sympathetic regulatory disturbances. One case simulated an infectious disease (typhoid). As the cause of the formation of the aneurysm, the author assumes a weakness of the vascular wall, which in turn is due to embryonal malformations of the arteries at the base of the brain. The rupture was probably caused by fluctuations in the blood pressure. The simultaneous existence of a coronary infarct in one of the cases makes it appear probable that a generalized vascular disorder, perhaps of a functional nature may exist in cases of subarachnoid hemorrhage. The author's observations are a warning that a therapeutic spinal (lumbar) puncture

should be strictly limited to the cases in which it seems absolutely necessary, for instance, if a considerable central increase in the blood pressure exists.

Salicylic Acid Administered Percutaneously—Gehlen and Blankenstein demonstrate that the action of percutaneously administered salicylic acid preparations is limited to from two and a half to three hours, which time is equivalent to the duration of the skin-tissue passage of the preparations and it also corresponds to the results of the biologic investigations by Brandt, who showed in stained skin sections that the same time was required for an accumulation of the salicylic acid in the canal system of the corium and of the epidermis. After that the salicylic acid was absorbed by the dilated blood capillaries and was eliminated by way of the kidneys. Moreover, the time corresponds to the period of alleviation of pain reported by the patients with various rheumatic disorders. Therefore, in order to obtain permanent results, the percutaneous application of salicylic acid preparations must be repeated at intervals of from two to three hours, for in this manner an interruption of the analgesic action is prevented.

Study of Etiology of Hyperthyroidism—Eitel attempted to investigate the relation between the thyroid and the nervous system and to determine the role of the latter in the genesis of hyperthyroidism. Studies by others have revealed the presence in the anterior lobe of the pituitary of a substance capable of inducing in an animal a state of hyperthyroidism. Administration of this substance induces typical anatomic alterations in the thyroid, increased basal metabolic rate, diminution of liver glycogen, diminution of iodine content of the thyroid and increase in the iodine content of the blood. The author took advantage of this thyreotropic effect in evaluation of the influence of the nervous system in the production of certain diseases of the thyroid. The following observations were made: (1) the effect of the anterior pituitary on the thyroid when the cervical sympathetics were removed, (2) the effect of the anterior pituitary on the surviving gland, and (3) the effect of the anterior pituitary on transplanted thyroid. The results obtained were as follows: 1. When the cervical sympathetics were extirpated, the thyroid exhibited on administration of large doses of the anterior pituitary the characteristic alterations of hyperthyroidism. Its reactivity to small doses was somewhat lowered. 2. The surviving thyroid reacted in the same manner to the administration of the thyreotropic substance. 3. The autoplasmic and homoplasmic thyroid transplants reacted in the same manner to the thyreotropic substance. Signs of hyperthyroidism were well developed in three and four week transplants. From these experiments it is apparent that the stimulus for the pathologic increase of thyroid function is to a great extent independent of the nervous system. The possibility of influencing at will the functional activity of a transplanted organ was demonstrated in these experiments. The possibility of treating athyreosis by transplantation of the thyroid is suggested.

Injuries of Knee—According to Jirásek, injuries of the lateral ligaments and capsule of the knee joint result from a great force applied either in abduction or in adduction, or from twisting of the one joint while the other is fixed. The alterations produced by trauma consist of stretching, splitting of the fibers and tearing away from the insertion with or without a piece of bone. The joint capsule tears in an irregular

manner and the edges of the torn surface are usually compressed. Isolated lesions of the lateral ligaments are rare and, as a rule, they are associated with injuries of the joint, the crucial ligaments and the menisci. The bone, as a rule is not involved. Among the objective signs characteristic of the condition are looseness of the joint, increased lateral passive mobility of the leg and tenderness or a palpable depression at the point of injury to the lateral ligament. The roentgenogram in early cases frequently shows particles of bone torn off with the ligamentous attachment and in older cases a paracondylar osteoma. The prognosis in milder cases is good without operative intervention, but in extensive and complicated lesions an early operative intervention becomes necessary. Its aim is the repair of all injured parts, suture of the lateral ligaments, plication suture or a plastic procedure on the crucial ligaments and removal of a torn meniscus. The author advises a longitudinal incision curved below, careful opening of the joint and a tight closure of all layers. The average duration of disability was from two to three months. Of thirteen patients operated on, eleven had excellent results.

Influence of Anesthesia on Circulation in Thyrotoxicosis—Neter shows that rabbits with severe thyrotoxicosis which have been anesthetized in a degree adequate for normal animals, show spontaneous and reflex movements, increased blood pressure and fluctuations in the blood pressure. There also exists a disturbance in the reflex autoregulation of the circulation, for increase of the blood pressure in case of exclusion of the pressoreceptor nerves and decrease of the blood pressure in case of their stimulation are inadequate. The author wanted to determine whether this failure of the reflex autoregulation is due to a change in the reflex arc itself or to a disturbance in the sympathetic nervous system resulting from an abnormal irritability. It was found that additional anesthesia counteracts the spontaneous and reflex movements and brings the increased blood pressure down to normal, and that the reflex autoregulation takes the normal course. This indicates that the additional anesthesia abolishes a disturbance that inhibits the reflex autoregulation of the circulation that is, the abnormal irritability. Since human thyrotoxicosis also is accompanied by a disturbance in the reflex autoregulation of the circulation, which most likely is due to a pathologic irritability, the treatment of exophthalmic goiter with anesthetics and hypnotics gains importance for the removal of sympathetic functional disturbances.

Agglutination of Staphylococci by Blood Plasma—The studies reported by Birch-Hirschfeld concern the following problems: (1) parallelism between the coagulation of plasma and the agglutination reaction of staphylococci; (2) the agglutinating constituents of the plasma and (3) the relationship between agglutination and coagulation activation. She found that staphylococcus strains which coagulate citrated plasma, become agglutinated by this plasma. Thus the agglutination test presents a simple method for the differentiation of staphylococcus strains. The agglutinating action of the plasma is due to its content in prothrombin. For this reason it is absent in 'pure' fibrinogen solutions or serums, but it is present in

fibrinogen solutions and in serums that contain prothrombin. The reaction may be abolished by the influence of calcium chloride. Agglutination and coagulation activation are, to a certain degree, independent of each other, for instance, the agglutination may be inhibited without abolishment of the coagulation, and vice versa. The author discusses the biologic significance of the reaction. She points out that agglutination reveals clearly the affinity existing between prothrombin and parasitic cocci. This phenomenon is a manifestation of the adaptation between the parasite and the mammalian organism. It is probable that this affinity plays an essential part also in coagulation, even if agglutination as such is inhibited. Thus the process of plasma coagulation is brought into relationship to biologic processes already known.

Aphthoid—The child observed by Kumer had severe burns in the region of the buttocks and died on the fifteenth day after the accident. On the second day after the burns had been sustained, a severe toxic exanthem developed on the trunk and the extremities and on the twelfth day the symptoms designated as aphthoid became manifest. Thick-walled vesicles on a slightly infiltrated and reddish ground appeared on the nasal openings and on the mouth. The oral mucous membrane in other cases often involved remained free in this instance. The literature on the etiology of the aphthoid indicates that the condition is probably caused by a virus and that a relationship exists between herpes simplex stomatitis aphthosa and aphthoid. Animal experiments conducted by the author with aphthoid material from the patient observed by him indicate that the material contained herpes virus. He thinks that if it should be proved that the herpes virus is actually the cause, the aphthoid would present so to speak, the ecthyma form of the otherwise harmless herpes simplex.

Bovine Tubercle Bacilli, Lupus Vulgaris and Pulmonary Tuberculosis—Hamel relates the history of a girl with lupus foci on the face neck and extremities. Material from a lupus focus was injected into guinea pigs and the animals developed a generalized tuberculosis which proves that the tubercle bacillus was of the bovine type. Two years later the patient was again admitted to the hospital because of recurrence of lupus foci and roentgenoscopy of the lungs revealed a bilateral cirrhotic pulmonary tuberculosis. Examination of the sputum by the animal test indicated that it contained bovine tubercle bacilli. The author says that in Germany about 10 per cent of the patients with lupus are infected with the bovine type of the tubercle bacillus. In patients with pulmonary tuberculosis however the bovine type is found much less often, namely in only 0.5 per cent of the cases.

Skin Diseases of Milkers—Gotttron calls attention to "milkers' nodules," which were better known before the eradication of smallpox and are probably caused by a vaccine virus. From this type of nodules he differentiates telangiectatic granulomas, which are not pediculated on the fingers of milkers as they are in other persons. The absence of the pedicle may be due to the frequent compressions to which these formations are exposed on the hands of milkers. The author calls particular attention to nodular formations that are caused by the penetration of cow's hairs. These nodules vary in size between a grain of rice and a pea. They are bluish red and at the top may have a small scab or a necrotic layer. Occasionally hairs stick out from these nodules. Another disorder caused by the penetration of cow's hairs is a spindle shaped thickening of the entire phalanx, and then there are the granulomas that develop in rhagades that have become irritated by the penetration of cow's hairs. The author describes the histologic aspects of the granulomas caused by cow's hairs, and he suggests that in order to differentiate this type from milkers' nodules, the term milkers' granulation nodules should be applied to them. He considers surgical measures the best treatment for these nodules.

Diagnosis and Therapy of Pulmonary Abscess and Gangrene M. Weinberger—p. 398

Pathogenesis of Acute Diseases of Pancreas—Popper shows that an inflow of pancreatic secretion into the bile passages can be observed in nearly all acute disorders of the pancreas. If there are disturbances in the discharge at the papilla, a trypsin activation takes place in the biliary passages, and it spreads from the distal intrapancreatic portion of the choledochus to the pancreas. This tallies with the pressure of the secretion in the pancreatic duct and in the bile duct and makes it understandable why in most cases of pancreatic diseases that come up for necropsy the pancreatic duct shows no changes. It harmonizes also with the close relations between gallstone disease and pancreatic disorders, since the disturbances in the discharge are caused generally by papillary concretions or by spastic conditions at Oddi's sphincter, which in turn are the result of disorders of the gallbladder or of the bile passages. The author rejects an etiologic separation between pancreatitis and necrosis of the pancreas. He maintains that they are only different stages and different reactions of the same disease process, and the secretory phase of the pancreas that is, the presence in the cells of larger or smaller amounts of trypsinogen at the onset of the pancreatic disorder, plays an important part in this process. Biliary peritonitis without perforation involves the same pathogenic factors as does acute pancreatitis, however it can develop only if acute pancreatitis does not, for the two diseases exclude each other to a certain extent. The author thinks that his explanations apply to the majority of acute diseases of the pancreas but admits that a relatively small number of acute pancreatic disturbances must be ascribed to other pathogenic factors.

Short Waves in Treatment of Angiotrophoneurotic Symptoms—In employing short waves in treating patients with angiotrophoneurotic symptoms Weissenberg observed that, when large amounts of energy were applied painful conditions often became acutely exacerbated, while the use of small amounts of energy often effected a noticeable and sometimes instantaneous improvement. The various wavelengths between 4 and 17 meters occasionally produced different effects but the differences were not constant. Patients with acroparesthesia and Raynaud's disease felt considerable relief already during

the treatment, while in endarteritis obliterans and in severe forms of gangrene the pains were often greater than before. The effects of the short wave treatment were particularly favorable during the cold months. In a patient with Raynaud's syndrome, short wave treatments of the hands had practically no effect but irradiation of the midbrain produced considerable improvement. The author found that diabetes mellitus is not necessarily a contraindication to short wave therapy. In endarteritis obliterans and in gangrene, only prolonged treatment with large amounts of energy was successful, and occasionally even this method failed. The short waves were successful in a large percentage of cases showing angiospastic disorders such as migraine, angina pectoris, dysmenorrhea, asthmatic conditions and colics. The number of irradiations that were required until results could be seen varied between eight and sixty. The author concludes that short wave therapy of angiotrophoneurotic symptoms is highly promising, is without danger and gives the patient great relief.

Calcium-Methenamine Compound in Influenza—Kofler states that in the course of the last ten years he treated influenza of the upper respiratory tract with a double compound of calcium and methenamine. When the patients applied for treatment, the influenza had generally entered the chronic stage, for most of them had tried self treatment during the acute stage. As a rule the compound of calcium and methenamine was given internally in the form of tablets or of a solution and it was given by injection only in cases in which it caused gastro-intestinal disorders. The daily dose as well as the total dose is determined on the basis of age, sex and general condition. Children are given about half of the amount taken by adults and women, who apparently do not tolerate methenamine as well as men do, are given somewhat smaller daily doses than those given men. During the chronic stage, adults are given from four to six tablets daily, but in the incipient stage, when there is still a prospect of checking the process, twice as much may be given. The preparation may be used also for prophylactic purposes at the time of an influenza epidemic, when about three tablets may be given daily. The author thinks that the calcium content of the compound aids the action of the methenamine and largely prevents the complications that may be produced by the methenamine.

Salt Water Therapy of Chronic Uremia—Von Farkas says that for this treatment to be successful in chronic uremic renal diseases the kidneys must still be capable of a daily diuresis of 2000 cc., a certain functional capacity of the heart is likewise required. The salt water therapy is particularly promising in cases in which the heart has not been impaired by a prolonged hypertension. Since it is of vital importance that the quantity of urine be kept high for a large part of the day, it is not sufficient to let the patient merely take large amounts of water, either the water intake should be well distributed (about 50 cc. every half hour) or care should be taken that the water is slowly eliminated by the addition of small amounts of sodium chloride. Ringer's solution or physiologic solution of sodium chloride is suitable for the latter purpose. Soups

having the usual salty taste likewise contain approximately 0.5 to 1 per cent of sodium chloride. In cases of uremia in which the sodium chloride content of the blood is abnormally high it is advisable to give pure water, if the sodium chloride content is normal or reduced, salt solutions are advisable. Occasionally the administration of the salt solutions may result in edema, but this does not necessitate an interruption of the treatment, for if ordinary water is given in such cases an excessive diuresis is generally the result and it is often accompanied by the elimination of large amounts of nitrogen. It was also observed that the patients frequently feel better when, by the administration of large amounts of water, edemas are produced and the retained nitrogen substances are thinned out. The salt water therapy does not make superfluous the other therapeutic measures that have proved valuable in uremic conditions. Sugar infusions, calcium injections, venesection, intestinal irrigations and limitation of the nitrogen intake are by no means to be abandoned. The sodium chloride content should be kept under constant control in the course of the treatment. The author illustrates the favorable effects of his treatment with a number of case histories.

Blood Cholesterol in Diabetes Mellitus—Grieshaber found that there exists a hypercholesterolemia in progressive cases of diabetes mellitus showing severe metabolic disturbances. With the improvement of the metabolic condition the hypercholesterolemia improves particularly under the influence of insulin therapy. Modification of the carbohydrate metabolism by the administration of dextrose, insulin or epinephrine causes the total cholesterol content of the blood to show fluctuations of a certain regularity, but insulin and epinephrine do not seem to influence the cholesterol content of the blood directly. In severe cases of diabetes mellitus the degree of hypercholesterolemia seems to furnish a suitable indicator for the metabolic disturbance and for the efficacy of the insulin therapy, but in mild cases the cholesterol content of the blood does not permit conclusions.

Gastrojejunocolic Fistula After Stomach Resection—The most frequent complication of the peptic jejunal ulcer according to Koch and Belozerkovsky is penetration into the neighboring viscera, most frequently the mesocolon and the transverse colon. This complication has received but little attention. Kotzoglou collected, up to 1929, 117 cases. The operation indicated for this condition is a formidable one especially when resection of the transverse colon becomes necessary. If left to itself, however, the condition invariably is fatal. The authors report 427 resections of the stomach for ulcer, with a mortality of 63 per cent and a peptic jejunal ulcer in 3. Of the latter, two developed a gastrojejunocolic fistula. They conclude that even an extensive resection does not always exclude the development of a peptic jejunal ulcer. In the first case the total acidity was 62 and free hydrochloric acid 56, and in the second they were 70 and 50, respectively. The mechanical trauma to the jejunum from the use of clamps is an important factor in the genesis of the peptic jejunal ulcer. The authors, therefore, in operating apply a clamp to the stomach but not to the jejunum. The gastroduodenal fistula unless operated on, invariably is fatal.

Results of Splenectomy—Tammann and Deutelmöser report the late results of twenty-seven splenectomies from the surgical clinic of the University of Göttingen. Attention is called to the presence of Jolly bodies in the red cells after a splenectomy in otherwise healthy persons. The erythrocyte count and the hemoglobin remained in their late cases well within the normal limits. There was no increase in the resis-

tance of the erythrocytes to salt solution. The platelet count and the coagulation time were normal. Disregarding traumatic injuries to the spleen, in which splenectomy constitutes a vital indication, the best results, approximating a permanent cure were obtained in hemolytic icterus and, next, in Gaucher's disease and in essential thrombopenia in which the main clinical symptoms were absent years after the splenectomy. The same can be said of splenic tumors resulting from hepatosplenic disease (Banti). The question of splenectomy for splenic tumors of leukemic origin presents itself only in exceptional cases while its removal in pernicious anemia has been generally abandoned.

Operative Treatment of Pylorospasm in Nurslings—Ochler reports forty-two cases of pylorospasm in nurslings on whom operation was performed in the last fifteen years. The patients ranged in age from 26 days to 5 months. The average age was 2 months. Four fifths were boys and one fifth girls. There were six fatalities, a mortality of 14 per cent. Three of the patients were in a much debilitated state when operated on. Of the thirty-six surviving patients, thirty-four were followed up. The immediate result of the operation was always a prompt cessation of vomiting. The late results were excellent so far as gastric function was concerned. The general health of these children was satisfactory and there were no developmental disturbances of any kind. The author believes that the results of the operation may be further improved by attention to complete division of the entire involved circular muscular tumor and by what is even more important, the timely operation.

Unexpected and Sudden Death in Childhood—The material reported by Siwe comprises 212 cases of sudden death, exclusive of deaths due to accidents or injuries connected with delivery, from 1916 to 1932, in children up to 15 years of age, 143 occurring during the first four months of life. Neither sex predominated. The seasonal incidence showed about the same course as the disturbances of the respiratory organs, and the majority of positive pathologic results were established in these organs. He emphasized that such disorders do not always give local symptoms and are consequently easily overlooked. A simple cold or slight intestinal disturbance may lead to vomiting with aspiration, quickly causing death. During the first three months of life there is greater possibility of disease of the brain through most varied infections and intoxications. Even in breast-fed infants, inanition may occur and doubtlessly contribute to death. Enlargement of the thymus could not be established as the cause of death. In cases presenting such enlargement the symptoms before death and the results after death were the same as in children with a thymus of normal weight. In rare cases, however, the author says considerable enlargement of the thymus may lead to symptom from the respiratory passages. Thirty cases are reported.

CONVULSIONS IN CHILDHOOD

M G PETERMAN, MD
MILWAUKEE

In May 1932 I¹ reported the results of a study of convulsions in children. A new classification was presented with the hope of offering some assistance in the understanding and in the diagnosis of the convulsive states. At the suggestion of Lennox, a further study was made of the case histories reported particularly in regard to the age at the time of the first convulsion. The information obtained together with the data on eighty-one additional cases necessitates a revision of my classification.

This revised classification is presented on the basis of 500 cases in children who were brought to the hospital or to the office in the past nine and one-half years because of convulsive seizures. As stated in the previous report only those cases are included in which a complete study was made. This includes a careful physical examination usually a period of observation, a neurologic examination a complete blood count, such blood chemistry (determinations of the calcium phosphorus, nitrogen, sugar and dextrose tolerance, and the like) as is deemed necessary, urinalyses examinations of spinal fluid, encephalograms when indicated examinations of the fundi roentgen examinations, stool examinations and the like. Many cases were studied for months before a diagnosis was made. In some cases (thirty-two) I was unable to make a definite diagnosis after I had exhausted the facilities at my disposal. These cases are listed as "cause unknown." In thirty-four cases the age at the time of the first convulsion could not be obtained. These are listed in the entire series (table 1) and again separately in table 2.

Under "cause unknown" are possibly included some unrecognized cases due to sinus thrombosis, allergic reactions, hypoglycemia and hyperinsulinism. The absence of these diagnoses does not indicate errors of omission. No such diagnosis could be established in the thirty-two cases in which the condition was in doubt.

Sinus thrombosis was a likely cause in some of the cases associated with or following gastro-enteritis but it was not possible to be definite. Byers and Hass² made a study of fifty cases of thrombosis of the intracranial venous sinuses in infancy and childhood. The infants with primary thrombosis did not present a typical clinical picture but were usually diagnosed as

having an acute nutritional disturbance. The physical examination was often negative except for severe dehydration. Convulsions were common in the second week and were usually sudden in onset and jacksonian in type. The diagnosis was seldom made ante mortem.

It is probable that some allergic conditions may cause edema of the brain and thus produce a convulsion.³ I was not able to recognize the presence of such a condition in any case.

Cases of convulsions due to hypoglycemia and hyperinsulinism have been cited in the literature.⁴ Whenever the history was at all suggestive in my cases, i. e., when the seizures occurred early in the morning, particularly after a twelve-hour fast or longer, or when they occurred consistently before or at meals, special examinations such as blood sugar determinations and dextrose tolerance tests were made. Several children have been referred to me with the diagnosis in point but the observations have not been conclusive. The following is an illustrative case.

CASE 1—A girl, aged 9 years, complained of short spells of unconsciousness (petit mal) occurring about once a month for the past one and one-half years. These seizures have been increasing in frequency and severity, until three weeks before admission there was a grand mal attack. The attacks are often (not always) associated with exhaustion, they occur more often before meals. Following the attacks there is fatigue and usually a frontal headache. The father and the father's father, mother and sister have or have had migraine. The patient's sister, aged 7 years, also has had migraine for one year and often has attacks of headache and vomiting following her sister's attack of petit mal.

Physical examination by a number of pediatricians, an endocrinologist several internists a neurologist and an ophthalmologist revealed no abnormalities of any significance. A proctologist was called in because of some blood in the stool, and a papilloma was removed from the rectum.

The child weighed 65 pounds (30 Kg) and was 52¼ inches (131.6 cm) in height. Her nutrition was good, her mentality was normal and her progress in school was normal.

Laboratory examinations showed urinalyses, normal, blood counts, normal. The basal metabolic rates were within normal limits. Roentgenograms of the skull were negative.

May 27 1933 a dextrose tolerance test was made elsewhere with the following report:

8 30 a m fasting, 53.3 mg
8 50 a m dextrose 50 Gm
9 35 a m blood sugar 57.8 mg
10 20 a m, blood sugar 63.2 mg
11 05 a m blood sugar, 67.9 mg
11 50 a m. blood sugar, 48.5 mg

From the same clinic it was reported that 'an allergic review showed a sensitivity to various foods and following their removal there has been no improvement.'

Examinations in my service at the Milwaukee Children's Hospital, June 12, showed skin tests negative to all food extracts

June 14, roentgen examination of the stomach and small bowel (Columbia Hospital, Dr S A Morton) gave the following results. The esophagus was normal. The stomach was normal in size and position. Peristalsis was normal. The duodenal cap filled well and there was no radiographic evi-

June 22, the spinal fluid was clear and under no increased pressure. It contained 2 cells, no globulin, and 53 mg of sugar. A test for colloidal gold was negative. A blood sugar count taken at the same time was 113 mg (capillary blood—Gibson method).

June 24, blood taken immediately after a seizure showed a sugar value of 74 mg (micro Gibson method on capillary blood).

July 4 blood taken immediately after a seizure showed a sugar value of 66 mg (macro-Folin-Wu).

June 21, the child was put on a fasting diet.

July 3, she was put on the ketogenic diet.

July 6, she was given 10 units of insulin at 8:45 a.m. after a breakfast at 7:30 a.m. There was no reaction. At 4:30

dence of lesion in the stomach or duodenal bulb. The duodenum was well outlined under the fluoroscope and by plates, and at no time was anything seen suggesting any pathologic condition in the region of the duodenum. The stomach emptied normally, as a plate taken after one and one-half hours showed that the stomach was practically empty and the barium was distributed throughout the small bowel as far as the cecum. A plate taken after five hours showed all the barium in the colon.

There was no roentgenographic evidence of lesion in the stomach or small bowel. The shadow of the kidney on the right side was larger than that on the left and seemed a little larger than was usually seen in a child of this age.

The results of dextrose tolerance tests are given in tables 3, 4 and 5.

June 15, the blood calcium was 14 mg per hundred cubic centimeter, the phosphorus 51 mg.

June 19 the blood calcium was 13.3 mg the phosphorus, 45 mg.

8. Treat basic cause

p.m. she was given 20 units of insulin without a seizure. At 5 p.m. the child had her evening meal and at 5:20 there was a reaction of nervousness, tremor and weakness but no seizure.

The diagnosis that I made in this case was idiopathic epilepsy based on the family history, the character of

the seizures and the temporary exclusion of an organic lesion

It is not my contention that cerebral sinus thrombosis, allergic reactions, hypoglycemia and hyperinsulinism do not cause convulsions in children. I wish merely to state that I have been unable to establish such a diagnosis in my series of cases.

Criticism has been made that I have placed the entire blame of seizures on a single cause.⁶ This is a misunderstanding. In a previous communication I stated "The infant and the child are subject to certain diseases, which in themselves are the exciting factors or indirect causes of convulsions. When the period of incidence of these diseases is passed, and thus the exciting causes are removed, the incidence of convulsions is greatly lowered."¹

It is obvious that a convulsion is only a symptom, the final explosion of a complex reaction, the trigger mechanism of which may be a number of factors. However, the same stimulus applied to a group of children will elicit no consequential reaction in the normal subject but a characteristic type of convulsion in the patient with tetanus, another type in the epileptic, and still another in the infant with spasmophilia. I wish simply to point out that there are certain disease entities which create in the patient a susceptibility to the convulsive state. The banging of a door may set off the seizure, but when the tetanus infection is gone, when the spasmophilic patient's blood calcium and phosphorus are normal, the same stimulus will not produce a convulsion. Lennox has nicely detailed the multiple causes of a seizure, which I believe applies to most con-

vulsive disorders.⁵ His report of psychic or emotional causes of a convulsive disorder gives me courage to report the following case.

CASE 2—A girl, aged 4 years, was admitted, May 27, 1929, shortly after she had had her right forearm and hand caught in an electrical clothes wringer. There was an abrasion of the skin on the forearm, edema and marks of contusion but no fracture. The injury was treated and the child sent home May 28, the child had a convulsive seizure which began with

pain in the right forearm, the face was "drawn to one side," the eyes rolled, and the right arm twitched. Two and one-half weeks later there was a second, similar seizure. In July there were two and in August three seizures. September 1 there was another seizure, which lasted five minutes, after which the child was brought into the hospital. Examination revealed scars on the right elbow. The urine and blood count were normal. The Mantoux tuberculin test (with 0.001 mg of old tuberculin) was negative. The Wassermann and microprecipitation tests were negative on blood serum and spinal fluid. The spinal fluid was clear and under no increased pressure, globulin was normal, the sugar value was 63 mg and culture was negative. The neurologist found nothing abnormal. A lateral roentgenogram of the skull showed no abnormalities.

The family history in this case was not positive. She was a full term child, of the second pregnancy, weighing 9 pounds (4,082 Gm), born after a long labor, with forceps. She sat at 5 months, talked at 11 months and walked at 12 months. She had had a mild case of measles with no complications or sequelae.

My diagnosis in this case was jacksonian convulsions due to brain injury (?). The psychic trauma seems responsible for the injury (?), which might be called by Krasnogorski a "functional ulcer of the brain."⁶

Opening in left parietal region of skull in case 3

The following case will be of medicolegal as well as of scientific interest.

CASE 3—A girl, aged 2½ years, admitted, June 25, 1927, had fallen from a second story window onto a sidewalk, June 15. She was unconscious when picked up and was taken to the Emergency Hospital. Examination there revealed a hematoma of the left parietal region and bleeding from the nose and mouth. Three hours after admission, spinal puncture yielded a bloody fluid under great pressure. Convulsions of the right side of the body developed. Operation revealed a linear fracture in the left parietal region with gaping of the edges. A fragment of the skull 1 inch (2.5 cm) in diameter was separated and removed. After operation she regained consciousness and showed a marked improvement. Six hours later she had a sharp rise in temperature and a return of convulsions on the right side. June 25, she was transferred to the Milwaukee Children's Hospital. July 1 there was an occasional tonic spasm and partial paralysis of the right arm and leg and a partial central paralysis of the right side of the face. The right pupil was larger than the left. There was a bilateral ankle clonus and a positive Babinski reflex on the right. The fundi were normal. The urine and blood count were normal and the Wassermann reaction was negative.

April 5, 1928, the child was readmitted for an acute infection of the upper respiratory tract. At that time there was

⁵ Lennox, W. G. New England J. Med. 209:386 (Aug. 24) 1933.

⁶ Krasnogorski, N. I. Psychology and Psychopathology in Childhood as a Branch of Pediatric Investigation. Acta Paediatr. 11:499 1932.

noted a bulging, pulsating hernia through the opening in the left parietal region of the skull, as shown in the accompanying illustration. There had been no seizures and there was no paralysis. Dec 7, 1931, the child was brought back with the complaint that for two months she had had spells when the right leg would give way, causing her to fall. In these attacks the right arm twitched and the eyes and mouth were drawn to the right. She was unable to talk during the seizure and there was loss of sphincter control. After the attack she would sleep for half an hour. These attacks occurred three

or four times a week without an aura. Occasionally there was sudden projectile vomiting half an hour after the seizure. Examination revealed the cerebral hernia previously described. The gait was normal. There was marked exaggeration of the patellar reflexes and some ataxia of the right arm in the finger to nose test. Blood pressure was 110 systolic, 74 diastolic. The spinal fluid was normal.

Thus there was an interval of four and one-third years between an injury to the brain and the resultant jacksonian convulsions. While I have observed intervals of three years between a difficult birth and the resultant convulsions, case 3 presents the longest interval between the injury and the resultant convulsive seizures in this series. In all three of the foregoing cases a multiplicity of factors may have contributed to

set off the mechanism of the convulsive seizure, but the pathologic basis that was responsible for the liability to convulsions is clear.

Finally, there are certain families in which the incidence of convulsions in childhood is particularly high. Case 4 is one of such a group.

CASE 4—A boy, aged $3\frac{1}{2}$ years, of the second pregnancy, had a normal birth after five hours of labor. There had been normal development. At 17 months the patient had one seizure with tonsillitis, at 20 months there was a recurrence of tonsillitis but no seizure. At 21 months there was severe grand mal when he fell to the floor, he became cyanotic and frothed at the mouth and subsequently had a deep sleep. A third convulsion occurred two weeks later and a fourth after eight weeks. There was a free interval of seven months, after which four convulsions developed at intervals of from two to three weeks. Urinalysis was negative and blood counts were normal. The blood calcium was 12 mg and phosphorus 7.2 mg. Blood sugar after a twelve hour fast was 93 mg. The fundi were normal. Roentgenograms of the head and chest were negative. Skin tests were negative to all common foods.

The family history is important. The child's mother's third cousin was diagnosed as epileptic. The child's father had nine convulsions in early childhood, but none since. His father's mother's family included fourteen members who had had convulsive seizures in early childhood, one cousin had had about 100 seizures before she was 8 years old, at which time they stopped. She is now 33 and has a child who had convulsions in early childhood. One of the father's brothers had migraine.

In this case the heredity provides an excellent basis for the diagnosis of epilepsy. However it is questionable whether the same diagnosis would apply to all the members subject to convulsions. It is only when the convulsions recur and after various unrelated (?) stimuli and when all organic lesions are excluded that the diagnosis of idiopathic epilepsy may be made.

The treatment of convulsions remains the same as reported¹ (table 6).

SUMMARY

A revised classification of convulsions in 500 children demonstrates the basic diagnosis as epilepsy in 33 per cent of the cases, onset of acute infection in 22.8 per cent, cerebral birth injury or residue in 15.4 per cent, spasmophilia in 13.6 per cent, miscellaneous causes in 8.8 per cent, and cause unknown in 6.4 per cent (table 1). There was no recognized case of cerebral sinus thrombosis, allergic basis, hypoglycemia or hyperinsulinism in this series. Six and six-tenths per cent of the convulsions occurred in the first month of life (table 7), 13.6 per cent in the second five months of life (table 8), 40.2 per cent, the largest number, between 6 and 36 months of age (table 9), 26.4 per cent between 3 and 10 years of age (table 10), and 6.4 per cent between 10 and 15 years of age (table 11). In 6.8 per cent of the cases the age of the child at the time of the first convulsion could not be obtained (table 2).

324 East Wisconsin Avenue

Cause and Effect—It may seem to be beyond doubt that every effect must have a cause, and it is upon this assumption that we seek to cure a disease by the tracing of it to its cause, whether in the field of physical medicine or in that of the disorders of mind. It is suggested, however, that the hypothesis of cause and effect is not always valid in the way in which it is used and that in spite of its undoubted usefulness to scientific progress in the past it has by our wrong use of it involved us in a series of corrective fallacies also doing duty as hypotheses, which have obscured the true progress both of the science and the art of medicine.—Howe E. G. The Causal Fallacy, *Lancet* 1 611 (March 24) 1934.

ACUTE POSTOPERATIVE OBSTRUCTION
OF THE LOWER SMALL
INTESTINECARL B. SCHUTZ, M.D.
KANSAS CITY, MO

In the wide publicity that has been accorded the subject of intestinal obstruction, little attempt has been made to separate high obstruction from low obstruction. In the average discussion of either type both the symptoms and the treatment are based on a summation of observations made on the two types of obstruction. This has, I think, resulted in failure to appreciate several very important peculiarities in the symptoms and the general clinical picture of low obstruction. Indeed, I believe it largely accounts for the very unsatisfactory results that follow the occurrence of low obstruction as a postoperative complication.

If reliable statistics were obtainable I believe it would be discovered that the mortality of low obstruction is greater than that of high obstruction. Statistics on the subject of low obstruction are not accurate because the final diagnoses on hospital charts, from which data are obtained, are not confirmed by visual evidence (operation or necropsy) in a sufficiently large percentage to justify confidence in statistics so compiled. This statement is based on the fact that at St. Luke's Hospital, where this study was conducted it was only after the percentage of necropsies had reached the high figure of 94.2 (the second largest in the United States) that any suspicion of the frequency of low obstruction or the inaccuracy of its pre-mortem diagnosis was entertained. There is little doubt that the same discovery awaits other investigators whose studies are based on necropsy examinations of practically every case diagnosed as "peritonitis," "paralytic ileus," or the like.

The persistent appearance of these cases of low obstruction at necropsy prompted me to study a series of twenty-five in an attempt to discover some explanation for the failure to diagnose and to treat successfully this type of obstruction. I regarded it important to confine the study to those cases which had been examined at necropsy, because by such examination I could positively exclude the possibility of some condition other than obstruction as being a factor in the production of symptoms. Four of the patients in this series had been operated on to relieve the obstruction, five had had enterostomies performed, and ten had been treated expectantly by either constant or intermittent decompression with the nasal or stomach tube. The remaining six cases had been wrongly diagnosed and treated as peritonitis or paralytic ileus. Of most significance however, is the fact that, with the exception of two in which enterostomies had been performed, none of the cases had been diagnosed or treated early enough to hope for success. The results of the study that seemed important in the diagnosis of the condition are summarized in the accompanying table and will be discussed in some detail.

ANALYSIS OF LOW OBSTRUCTION

In considering the problems of the diagnosis and the treatment of low obstruction it is of value, I think, to divide low obstruction into two stages. Justification for such a division becomes obvious if it is recognized that low obstruction is a disease that follows a rather definite progression from a primary mechanical inter-

ference with the normal flow of intestinal fluid to a secondary series of pathologic, nonmechanical changes occurring in the walls of the obstructed loops which apparently produce and are followed by a fatal toxemia.

The normal intestinal tract may be compared to an elastic tube in which peristaltic movements maintain a constant flow of fluid in a caudal direction. When simple obstruction stops the flow of this fluid the only change that occurs is a mechanical damming back of the fluid above the point of obstruction. Since there is no interference with the production of the fluid in the obstructed loops, the volume of the fluid steadily increases above the obstruction. This increased volume mechanically dilates the intestinal walls and as a result sets up the mechanism of hyperperistalsis so characteristic of this stage of obstruction. The patient at this time complains of pain, distention, and sometimes regurgitation of greenish brown, practically odorless fluid but is otherwise in as good general condition as before the obstruction occurred. The innocuous character of the changes is further shown by the fact that there is no appreciable change in temperature, pulse, leukocyte count, urine or blood chemistry. On examination of the obstructed loops one notes that they are dilated and contain an excess of fluid but retain much of their normal firmness and elasticity and that the walls are translucent and of about normal color.

Within a variable time, however, the entire clinical picture changes. The patient, whose general condition such a short time before was comparatively good, shows unmistakable evidence of toxemia, characterized by listlessness, muttering delirium and fibrillary twitchings of the muscles of the face and the extremities. The abdominal distention increases and is associated with an almost constant regurgitation of brownish, foul smelling fluid. In contrast to the practically normal laboratory observations in the earlier period the temperature, pulse and leukocytes rise, the urine frequently contains albumin, and the blood chlorides rapidly decrease.

Examination of the obstructed loops at this time shows them to be greatly dilated and to have lost their previous elasticity and firmness. Indeed, they are so friable that frequently the slightest trauma will cause their rupture. From the stomach to the obstruction they have an opaque grayish or purplish appearance quite different from that observed in the earlier period.

In analyzing these two stages, or periods, of low obstruction it seems clear that in the early period the intestinal changes are essentially mechanical. All clinical symptoms as well as all pathologic manifestations seem due only to the fact that an obstruction to the normal, constant flow of intestinal fluid has occurred. With the exception of the hyperperistalsis, the intestinal changes could be duplicated by tying off a thin elastic tube through which a constant stream of fluid was caused to flow. Evidence of the innocuous nature of the changes is furnished by the good general condition of the patient. In the latter period, however, it seems equally obvious that the secondary changes in the obstructed loops have become of primary significance to the organism. Not only does the intestinal fluid change to a foul smelling, brownish substance, but the walls of the obstructed loops have a gross appearance suggestive of advancing degeneration. Indeed, from their color, their extreme friability and their opacity one gets the impression of an incipient necrosis. Paralleling the latter changes there develops a marked and progressive toxemia.

STAGES OF LOW OBSTRUCTION

Based on this conception of low obstruction, it would seem logical to divide the condition into two definite stages and to designate them as (1) the stage of obstruction, which begins with the occurrence of the obstruction, includes only mechanical changes, and ends with the supervention of the degenerative cellular changes in the obstructed loops and the appearance of toxæmia, and (2) the stage of degeneration which immediately follows the stage of obstruction, includes mainly cellular, nonmechanical changes and continues until the concomitant toxæmia causes death of the patient. Though the transition from the stage of obstruction to the stage of degeneration is often insidious, each stage is sufficiently characteristic from both a clinical and a gross pathologic standpoint to be readily differentiated. Indeed, I believe that division of low

obstruction into these two stages forms the only basis on which one can properly evaluate the symptoms of the disease and rationally institute its treatment.

ous to assume that the incision for operative surgery should be made, as is stated in many textbooks, at the point of maximum pain. In all the cases studied the obstruction was in the terminal ileum and yet, as shown in the table, the pain was almost as often in the upper part of the abdomen as in the lower part.

A most important characteristic of the pain of low obstruction is its persistence and its severity. In every one of the twenty-five cases reviewed it was necessary to give repeated doses of morphine to relieve the pain of which the patient persistently complained. In some instances this almost constant use of morphine was necessary for as long as five or six days. So constant was this observation that, even in a small series of cases, the conclusion seems justified that postoperative abdominal pain that is so persistent and severe as to require the repeated use of morphine should bring to

obstruction into these two stages forms the only basis on which one can properly evaluate the symptoms of the disease and rationally institute its treatment.

SYMPTOMS OF STAGE OF OBSTRUCTION

As shown in the accompanying table, there are two symptoms that are always present in the stage of obstruction. These are pain and abdominal distention. In addition to these two, but not occurring in all cases, is vomiting. Several observations made on each of these will be discussed in some detail.

Pain—The pain of low obstruction apparently begins with the occurrence of the obstruction. It is almost always of the familiar cramplike variety but occasionally according to the interpretation of six patients in this series, may be constant from the beginning. What has appeared to be a significant observation in this series is that the pain of obstruction has a tendency to become established in one portion of the abdomen. Whatever the explanation of this may be, it is important that its position bears not the slightest relation to the position of the obstruction. It is therefore errone-

mind the possibility of obstruction, despite the absence of other symptoms of the disease.

Hyperperistalsis—Hyperperistalsis accompanies the pain, of course, in the early stages of obstruction. Sometimes it is visible and almost always it is audible if investigated early enough. Once the stage of obstruction has passed, the typical rushing peristalsis disappears and is replaced by the "tinkling" type so frequently associated with peritonitis.

Uneven Distention—Abdominal distention always accompanies low obstruction. Indeed, it is the only symptom that is always present. Furthermore, it has one characteristic that is almost pathognomonic, viz., its unevenness. There are many who will doubt this and perhaps some who have never seen it. It is, nevertheless, present in practically every case of low obstruction and is without doubt the most valuable single clinical sign that the disease presents.

In the average case the unevenness of the distention is missed either because the attending surgeon does not take the precaution to remove the bandages from the

abdomen and look for the inequality of the distention in a strong cross light or because he takes this precaution too late. It may last a few hours or for a day or more but it must be emphasized that it is essentially an early symptom confined entirely to the stage of obstruction. Once it disappears it never returns. I am not aware of any other type of distention that so consistently bears this characteristic.

Vomiting—The third most frequent symptom of the stage of obstruction is vomiting. In the twenty-five cases studied, vomiting occurred in nineteen at some time during the course of the disease. In the remaining six cases, vomiting did not occur at any time. There is no particular significance in the fact that approximately 75 per cent of the patients vomited—that is well known—but it is significant that 25 per cent of the patients did not vomit, in fact, did not even have an excess of fluid in the stomach at any time during the course of the disease. In high obstruction, vomiting is almost always if not always present early in the disease and most certainly occurs at some stage. The fact that it may be absent throughout the entire course of low obstruction shows the fallacy of basing the diagnosis of low obstruction on observations made on high obstruction. Of particular significance in this regard is the fact that, with an average duration of the obstruction of 9.5 days, vomiting did not occur until an average of 4.2 days before the death of the patient. Thus it is seen that even in those cases in which vomiting did occur it often either appeared very late in the stage of obstruction or not until the stage of degeneration had probably become established. While conclusions based on statistics obtained from such a small series of cases may be misleading the implication loses none of its importance in emphasizing the danger of using the symptom of vomiting as a criterion for the diagnosis of low obstruction.

In textbooks, one of the most frequent symptoms given is "obstipation with no passage of gas by rectum." Nothing could be further from the truth. In the twenty-five cases studied, gas was passed by rectum in all but two up to the day of death. In some instances the passage of gas occurred only after the insertion of a colon tube, but in most instances it was passed without its aid. Whether this observation is a peculiarity to this particular series, only more experience will show. It is difficult to believe, however, that such would be the case. Seventeen of these twenty-five patients had bowel movements up to the day of death and in five of these diarrhea was a persistent and troublesome symptom. Since in many instances the so-called bowel movements were liquid stools consisting of material similar to that removed from the stomach, it may be assumed that the obstruction was not complete. It is, of course, highly improbable that post-operative obstruction is ever complete in its inception. However if one explains the passage of gas and fecal matter in these cases by the assumption that the obstruction was incomplete, one must also recall that all these patients died of their obstruction. Such an assumption is disproved, however, by the fact that, at necropsy, complete obstruction was found in all these cases.

It cannot be too often emphasized that one must not be misled by the relatively good condition of the patient during the stage of obstruction. It is a highly deceptive state that is of absolutely no prognostic value nor is it in any way reliable as a basis on which to judge the degree of the obstruction.

LABORATORY OBSERVATIONS

With the exception of the well known changes visible in the roentgenogram there are no reliable laboratory evidences of low obstruction that are characteristic of the stage of obstruction. The great value of the x-rays is generally realized but it is obvious that one must at least tentatively diagnose obstruction before the advisability of roentgen examination is apparent. It therefore should not be considered a substitute for careful, vigilant clinical observation. In this connection it may be parenthetically stated that the value of the x-rays in the diagnosis of low obstruction in any of its stages parallels the perfection of the picture.

STAGE OF DEGENERATION

The stage of degeneration is characterized by the appearance of a progressive type of toxemia. Usually the cramplike pain of the stage of obstruction is replaced by a pain more constant and less cramping. Often it is described as a full feeling and it is usually relieved by vomiting or the removal of gastric or duodenal fluid by the stomach tube. The distention is generalized and peristalsis is not visible, and if audible is "tinkling" in character. Sometimes in the very late period of the stage of degeneration the distention apparently decreases. It usually denotes a complete flaccidity and irreparable degenerative changes in the intestinal walls. The typical fluid of obstruction increases in almost direct proportion to the amount of salt solution administered. The progressive toxicity accompanying the stage of degeneration is evidenced at first by periods of delirium, tremor or stupor and often slight cyanosis, all of which temporarily disappear after the administration of salt solution. Later, however, salt solution has no effect on these symptoms.

It is in the stage of degeneration that the laboratory observations assume the characteristics so often quoted as typical of obstruction. The fever rises and the pulse increases. Usually there is an accompanying increase in leukocytes but in some instances a marked leukopenia develops, explanation of which is not clear. The well known decrease in the blood chlorides occurs in the stage of degeneration and is seldom, if ever, present in the stage of obstruction.

TREATMENT

As already mentioned, both the clinical and the pathologic changes that occur in the course of low obstruction suggest the occurrence of two stages in the progression of the disease. Whatever name one may choose to designate these stages is unimportant so long as it is recognized that in one (the stage of obstruction) there is nothing but a local change while in the other (stage of degeneration) the change involves the entire intestinal tract proximal to the obstruction and is accompanied by serious systemic toxicity. Recognition of this fact is essential to the rational and successful treatment of low obstruction, indeed, it is the very essence of its therapy.

Assuming the correctness of this conception of low obstruction, it becomes obvious that once the stage of degeneration is established the chances for successful results from any type of therapy decrease as the stage of degeneration progresses. It is because most of the surgery for low obstruction has been performed in this stage that in the minds and in the experience of many it is not only ineffectual but actually dangerous. Release of the obstruction in this stage is not only performed on a patient severely poisoned by the toxins accom-

panying the intestinal changes, is not only attempted on intestinal loops that are friable, tremendously dilated and atonic, but ceases to be a method of relieving the existing pathologic condition. The primary obstruction has been superseded by the secondary intestinal change and as a result has become a secondary item in the general therapeutic problem. Instead of treatment being directed to the comparatively simple mechanical problem of relieving the obstruction, one has in addition the almost insurmountable problem of restoring to physiologic function cells that have apparently begun to degenerate.

Therapeutic attention must therefore be mainly directed to the stage of obstruction, for it is here that the greatest chance for success lies. In this stage there are two methods of treatment that have various advocates, viz., (1) decompression of the dilated loops either by the Witzel tube (enterostomy) or continuous suction drainage through a duodenal tube and (2) relief of the obstruction by surgical means.

It has been repeatedly shown that the Witzel tube will drain but a small area of the intestine unless active peristalsis is present. It is evident that it is, however, usually employed in the stage of degeneration, for it is only in this stage that great amounts of fluid are formed and it is to remove the fluid that the tube is used. Furthermore at this time the intestine is dilated, filled with fluid and the patient too sick to withstand more surgery—a stage in which peristalsis, if present at all, becomes rapidly less active and soon disappears altogether. The suction duodenal drainage while more efficacious than the Witzel tube, obviously cannot possibly cure a complete obstruction. As both a preoperative and a postoperative measure or as a last hope measure in late cases, both procedures are of value in one way or another but neither is a substitute for surgery.

In low obstruction both methods have apparently saved certain patients and most patients have been benefited by their use. I think, however, that study will show that neither ever cured a persistent obstruction and I have no doubt that persistence in their use has often resulted in the attending surgeon waiting so long as to preclude success in subsequent surgical treatment.

Wangensteen and Paine¹ in their description of the treatment of obstruction by continuous duodenal drainage recognize its limitations. They clearly intimate that it is not a substitute for surgery and emphasize that it must be accompanied by careful observation to determine how long it may justify a delay for surgery. The method, so long as it is used with full realization of its purposes and its limitations, is a valuable aid in the treatment of low obstruction. The surgeon who persists in its use should realize that he is assuming that the existing obstruction is of the type that will spontaneously disappear and in so doing assumes greater responsibility than the surgeon who subjects his patients to early operation for relief of the obstruction.

In the experience of many, the treatment of low obstruction by surgery has produced disappointing results. This is due in the majority of cases, to the fact that surgery has been too long delayed. It is a safe assumption that the average patient with low obstruction is operated on several days after the stage of degeneration has become established. This state-

ment is based not only on personal observation and personal experience but on the fact that in the literature on the subject one finds frequent comments concerning "the desperately ill condition of the patient" and "the extreme friability of the obstructed intestinal loops," both of which are characteristic of the stage of degeneration but do not occur in the stage of obstruction. In the surgical treatment of low obstruction there are, however, certain details in technic which should be assiduously followed. The incision should be amply large and should be so placed as to give adequate exposure to all parts of the abdomen. In post-operative cases it is usually best to go through the former incision, since in all likelihood the obstruction has occurred at the site of operation. In order to get adequate exposure, complete relaxation, such as that obtained by spinal anesthesia, is essential. The continuous pulling and fumbling of the obstructed loops that occur when the incision is too small or the abdominal muscles are not fully relaxed is of serious moment and may, as the result of the shock it produces, be the direct cause of death.

CONCLUSION AND SUMMARY

If the observations in this series of cases are substantiated by those in similar studies the fact seems evident that improvement in the treatment of low obstruction depends primarily on improvement in its early diagnosis. As far as it is possible at present to tell, improvement in the diagnosis must come from a detailed study of the symptoms and clinical behavior of a large series of uncomplicated cases of low obstruction rather than from the development of some more or less specific laboratory device. It is clear, I think, that such studies of low obstruction must be predicated on the assumption that the onset, the progression and the symptoms of low obstruction differ in an important degree from those of high obstruction and that, therefore the two types of obstruction must be considered separately.

In the separate consideration of low obstruction it seems clear that it is both possible and logical to divide the disease into two stages. Since the first stage seems to be limited to only the mechanics of obstruction and to be accompanied by few evidences of any particular harm to the patient, it seems logical to designate it as the stage of obstruction. It also seems reasonable to designate the second stage as the stage of degeneration, since the gross pathologic changes in the obstructed intestinal loops seem to be of a degenerative nature and to be accompanied by toxic symptoms more or less characteristic of degeneration. The fact that the clinical manifestations of obstruction consistently parallel the pathologic changes in the obstructed loops suggests their close relationship and justifies estimation of the pathologic changes by the clinical observations.

In view of the comparative condition of the obstructed loops in the two stages of low obstruction, it is apparent that therapeutic endeavor should be largely directed to the stage of obstruction. In this period one has only to deal with a mechanical blocking of the normal flow of intestinal fluid, and there seems to be no serious change in the physiology of the cells comprising these obstructed loops. In the stage of degeneration however the comparatively simple problem of the relief of the obstruction is complicated by the supervention of serious and often advanced changes in the walls of the major portion of the small intestine. Indeed by initiating treatment in this stage one may be

¹ Wangenstein, O. H. and Paine, J. R. Treatment of Acute Intestinal Obstruction by Suction with the Duodenal Tube. J. A. M. A. 101: 1532-1538 (Nov. 11) 1933.

attempting to restore to physiologic function cells that are already necrobiotic

One of the earliest and perhaps the only specific symptom of the stage of obstruction is uneven distention. There are, no doubt, many who do not agree that uneven distention is an almost constant accompaniment of low obstruction. Though further observations are needed to demonstrate the correctness of this assumption, it is necessary to emphasize the fact that uneven distention occurs very soon after the onset of low obstruction that it is present for a short time only, and that it must be searched for to be found. The average surgeon looks on postoperative pain and distention as an expected consequence of abdominal surgery and as a rule, therefore, pays it little attention. It is useless to expect uneven distention after the stage of degeneration has begun for by that time the distention has become and will remain generalized, it is also useless to expect to discover the unevenness of the distention at any time unless all postoperative dressings are removed and a clear, unobstructed survey of the abdomen is made in a good cross light.

The symptoms of vomiting and "obstipation with no passage of gas by rectum," as frequently quoted in textbooks, are unreliable criteria on which to base the early diagnosis of low obstruction. While vomiting usually occurs at some time during the course of the obstruction, it is often absent in the stage of obstruction and, in fact, may not even occur in the stage of degeneration. It is unfortunate that because it is a constant accompaniment of high obstruction it should be thought necessary for the diagnosis of low obstruction.

However detailed one's analysis of the symptoms may be, the first essential in the diagnosis of low obstruction is that the possibility of its presence be kept in mind. It is perhaps the failure to do this that allows many of the diagnostic signs and symptoms to slip by without eliciting the careful consideration on which their proper evaluation depends. When the stage of degeneration has become established and the suggestive, if not characteristic, symptoms have passed unnoticed, one encounters the most difficult task of deciding whether or not the now generalized distention, the fever, the increased leukocytosis and the decreased or absent peristalsis are the result of peritonitis or obstruction. Certainly the high mortality attending low obstruction should dispel any ideas as to its being easy to manage and should stimulate a constant, informed and alert vigilance.

Any attempt to differentiate between partial and complete obstruction carries with it a grave responsibility. Unfortunately, it is not as simple as it may seem. The clinical criterion on which the diagnosis of partial obstruction is based is the passage of gas and fecal matter by rectum. Wangersteen and Paine contend that it can also be made by the roentgenographic detection of gas in the large bowel below the site of obstruction. The danger, if not the fallacy, of this criterion is shown by the fact that all but two of the patients included in this study passed gas up to the day of death. The obstruction was proved to be complete in all these cases by necropsy.

The conclusion seems logical that in most instances the treatment for low intestinal obstruction is essentially the surgical release of the obstructing lesion. Continuous suction drainage and enterostomy should be considered adjuncts to surgery rather than its sub-

stitute. The persistent use of continuous duodenal drainage or the prolonged confidence in the efficiency of drainage by enterostomy is necessarily accompanied by the responsibility for the assumption that the obstruction will spontaneously disappear. Only those whose experience with low obstruction has been very limited fail to recognize the magnitude of this responsibility. The dictum of early operation has been established by the experience of a great number of competent surgeons, but to this must be added the necessity for constant study and vigilance directed to the early diagnosis of low obstruction. Operation in the stage of obstruction should be followed by a definite decrease in the mortality of low intestinal obstruction.

QUININE AND ERGOT ALLERGY AND THROMBOCYTOPENIC PURPURA

REPORT OF A CASE

M. MURRAY PESHKIN, M.D.

AND

JULIUS A. MILLER, M.D.

NEW YORK

The clinical entity essential thrombocytopenic purpura (idiopathic or primary purpura haemorrhagica) is a condition of unknown etiology. A similar condition of known etiology is referred to as secondary or symptomatic thrombocytopenic purpura. Both these forms of purpura manifest a general hemorrhagic tendency, and the conspicuous feature is a definite diminution of the blood platelets. From the standpoint of treatment it is important therefore to determine if possible, by careful investigation the exciting causative factor of thrombocytopenia.

It is well to recall that there is also a number of conditions in which purpura occurs in the absence of a general hemorrhagic tendency and diminution of platelets. These purpuras according to Christian,¹ can be classified into essential (idiopathic) and secondary (symptomatic) nonthrombocytopenic purpura. The term purpura implies cutaneous hemorrhage. One of the important and clinically interesting subgroups of essential nonthrombocytopenic purpura is the so-called anaphylactoid purpura,² which includes the Schonlein-Henoch group and the Osler erythema group of skin lesions with visceral manifestations. Osler³ and Johannessen,⁴ among others, have commented that it seemed logical that an anaphylactic (allergic) reaction is responsible for the symptoms of essential purpura and serum sickness. Recent studies indicate that in this form of purpura there is a true allergy. Landsberger⁵ reported a case of purpura in an infant in whom cow's milk was the allergic offender. Alexander and Eyermann⁶ cited nine cases of Henoch's purpura due to food allergy. Barthelme⁷ and Kahn,⁸ among

8 Kahn I. S. Henoch's Purpura Due to Food Allergy J Lab & Clin Med 14 835 (June) 1929

others, also reported cases of Henoch's purpura due to food allergy. In each instance it was demonstrated that hemorrhage into the skin and other associated symptoms of Henoch's purpura were caused by the ingestion of particular foodstuffs.

Cases of purpura have been reported following a variety of drugs. Most commonly mentioned are aniline, iodine, pyridine, mercury, quinine, belladonna, ergot, acetphenetidin, salicylic acid and arsphenamine preparations. Probably most of these are nonthrombocytopenic purpura, but in some cases hemorrhagic purpura developed with a low platelet count following use of an arsphenamine preparation as in the cases reported by Thill,⁹ among others. Rosenthal,¹⁰ however, stated that besides arsphenamine such substances as benzene, aniline and quinine may poison the bone marrow in such a manner as to produce thrombocytopenia. It is evident from a survey of the literature that the vast majority of the cases of purpura due to drugs were considered from the point of view of a poison, and correctly so, because of the lack of evidences of their allergic nature.

The striking improvement that follows splenectomy especially in cases of the chronic form of essential thrombocytopenia first reported by Kaznelson,¹¹ is not obtained with any like degree in the cases of symptomatic thrombocytopenia. This improvement takes place even in the presence of a platelet count as low as before the operation. Hence the proper grouping of all types of purpura particularly thrombocytopenia, is extremely important and necessary for correct treatment.

The following report of a case is warranted not only because of its clinical interest but also because a definite causal allergic relationship between such drugs as ergot and quinine and thrombocytopenic purpura has been established.

REPORT OF CASE

H. R., a mulatto woman, aged 29, a waitress, unmarried, a native of the British West Indies, seen by one of us (M. M. P.) for allergic study, Feb. 27, 1933, had a history of bleeding from the gums and vagina along with large blotches under the skin, which occurred for the first time at the age of 14 years following the oral administration of some "drugs." She suspected pregnancy at that time.

Infancy and childhood had been normal except for some of the childhood diseases and "malaria, which everybody is supposed to have had." Quinine had been liberally administered with apparent tolerance.

The family history was negative to allergy.

At the age of 20 years the patient had taken only four doses of fluidextract of ergot each dose containing 4 Gm of the extract, at intervals of four hours, because of suspected pregnancy. The following day hemorrhage into the skin and mucous membranes occurred and persisted for nine days. In 1927 she complained for seven months of being "run down" with symptoms of numbness and tingling of the lower extremities, abdominal pains and backache. Her physician decided to administer a course of "tonic injections." The day following the first and only injection, profuse bleeding began from the gums and mucous membranes of the mouth and purpuric spots appeared on both legs. Although she had just completed a menstrual period bleeding began anew. Several days later blood appeared in the stools and urine. Sept. 9, 1927, one week after the onset of symptoms she was admitted to Fordham Hospital. The report of the positive observations at examination then showed bleeding from the mouth, with congestion of the pharyngeal and buccal mucosa, and on the left side near

Stenson's duct there were two ulcerations surrounded by a blood clot. On palpation the abdomen was tender throughout, with some localization in the region of the left lower quadrant. The stools on gross examination were tarry, while the microscopic examination revealed numerous red blood cells and no ova or parasites.

November 14, examination of the blood showed the bleeding time to be three minutes and coagulation time four minutes, along with an absence of clot retraction and a platelet count of 130,000. November 22 the bleeding and coagulation times were three and one-half and four minutes, respectively, and the platelet count was 142,000. On admission to the hospital the white blood cell count was 5,600 and the red cells numbered 1,800,000. Subsequent examinations of the blood showed gradual improvement and on November 26 the red cell count was 3,000,000 and hemoglobin of 70 per cent. Chemical examination of the blood showed nonprotein nitrogen, 42 mg., creatinine, 14 mg., and sugar, 105 mg. per hundred cubic centimeters. Roentgen examination of the bones of the lower extremities revealed no abnormalities. The blood pressure remained around 115 systolic and 60 diastolic. The medication consisted of the oral administration of calcium lactate and the hypodermic injection of iron cacodylate.

Discharged from the hospital, December 6, the patient was seen for the first time by one of us (J. A. M.) on December 13 suffering from bloody vaginal discharge and bleeding gums. Treatment was symptomatic and all bleeding ceased, December 18. She was again seen, Jan. 13, 1928, when she manifested all the signs of a hemorrhagic purpura. The treatment consisted of calcium lactate medication, local iodine application and ultraviolet irradiation. Bleeding ceased, January 18, but the treatment was continued for one month, the patient being discharged as cured February 18.

The patient seemed well from 1928 until Feb. 8, 1933, when she took of her own volition in the course of one day, 0.65 Gm (10 grains) of quinine sulphate with eight capsules of ergot (the dosage being unknown) for "delayed menstruation." That night bleeding from the gums and vagina with purpura ensued. She passed many blood clots from the vagina for two days. February 10 she was seen by one of us (J. A. M.), who sent the patient to Sydenham Hospital¹² for study. On admission the temperature was 101.4 F and the pulse rate 110. Physical examination revealed numerous ecchymotic areas and petechiae over the body involving particularly the skin on the chest and axillae. Both eyes showed a few patches of subconjunctival hemorrhages. There were dried clots of blood and free bleeding from the gums and mucous membranes of the lips and vagina.

On the morning of February 10 the blood picture showed a hemoglobin of 60 per cent, red blood cells 2,810,000, white blood cells 10,450, segment forms 65 per cent, band forms 26 per cent, small lymphocytes 7 per cent, monocytes and eosinophils each 1 per cent, platelets 130,000, coagulation time four minutes, bleeding time, eight minutes. There were present some toxic granules, achromia and microcytosis. In the evening the red blood cells were 3,180,000, white blood cells, 8,100 and platelets 100,000. February 14, the hemoglobin was 65 per cent, red blood cells 3,180,000, white blood cells 11,000, segment forms 45 per cent, band forms, 4 per cent, small lymphocytes, 37 per cent, monocytes, 7 per cent, eosinophils, 6 per cent. The microscopic appearances of the cells remained unchanged.

Examination of the urine February 13 showed only a faint trace of albumin and from 10 to 15 red blood cells per low power field and on February 14 the red blood cells ranged from 25 to 80 per low power field.

February 16 the patient was discharged from the hospital as "cured." Her condition was diagnosed as purpura haemorrhagica and intra-uterine gestation.

February 20 the patient had taken only three doses of 4 cc. (1 fluidrachm) each of elixir of iron, quinine and strychnine (N. F.) (each dose containing about 0.03 Gm [0.5 grains] of quinine hydrochloride). Bleeding commenced that night and lasted for two days. The patient was readmitted to Sydenham Hospital and on March 2 a therapeutic abortion was performed.

12 Gynecologic service of Dr. Alfred M. Hellman.

March 7, examination of the blood showed a hemoglobin of 69 per cent, red cells, 3 500 000, white cells, 6,050 segmented forms, 40 per cent, band forms 2 per cent, small lymphocytes, 48 per cent, monocytes, 8 per cent, eosinophils, 2 per cent, coagulation time four and one-half minutes and bleeding time, two and one-half minutes. August 1, when the patient was feeling well and was employed in her usual occupation, the blood picture showed a hemoglobin (Sahli) of 75 per cent, red cells, 4,400,000, white cells, 6,800, segmented forms, 46 per cent, lymphocytes, 46 per cent, monocytes 6 per cent, eosinophils, 2 per cent, platelets, 240 000, bleeding time two and one-half minutes, coagulation time, five minutes, and slight hypochromia.

Allergy Studies The cutaneous tests with ergot quinine alkaloid and quinine salts were performed and repeated at varying intervals with the following results:

Powdered ergot alkaloid and fluid extract of ergot showed negative reactions with the scratch test. A 1:50 solution of powdered ergot alkaloid extracted in buffered solution also showed negative reactions with the intradermal and passive transfer tests. (It is common knowledge that a person can be definitely allergic and yet be negative to cutaneous tests.)

The scratch test¹³ with quinine alkaloid 10 per cent hydrochloric acid and alcohol being employed as diluents, showed positive reactions ranging from one-plus to two-plus.¹⁴ Quinine sulphate (1 Gm of the salt is soluble in 30 cc of glycerin) showed a plus-minus reaction and quinine salicylate (1 Gm of the salt is soluble in 14 cc of alcohol) showed a one plus reaction. The water soluble quinine salts, such as the hydrochloride, dihydrochloride and bisulphate, all gave three-plus reactions. The intradermal test with a 1:50 extract of quinine alkaloid (10 per cent hydrochloric acid being used as the extracting fluid) showed a three-plus reaction the body of the wheal measuring 1.5 cm in diameter from which pseudopodia spread in all directions. The control with the extracting fluid was negative. When buffered solution was used as an extracting fluid, only a one-plus reaction was obtained. The quinine alkaloid and quinine salts are levorotatory. The dextrorotatory quinine derivatives, quinidine alkaloid and quinidine sulphate (soluble in alcohol) showed negative cutaneous (scratch and intradermal techniques) reactions. Passive transfer tests with a 1:50 extract of quinine alkaloid by the intradermal technique and with quinine dihydrochloride by the scratch test, each showed a one plus reaction.

March 29, 0.65 Gm (10 grains) of quinidine sulphate along with 0.001 Gm ($\frac{1}{100}$ grain) of strychnine sulphate and 1 cc (15 minims) of tincture of ferric chloride were orally administered without inducing any untoward symptoms.

Feb 10 1934, the patient was entirely well and the examination of the blood showed a hemoglobin of 83 per cent, red cells, 4,320 000 white cells, 6 000 segmented forms, 54 per cent, band forms 2 per cent, small lymphocytes 36 per cent, monocytes 4 per cent eosinophils, 4 per cent, platelets 210,000, bleeding time, three and one-half minutes, coagulation time, seven and one-half minutes.

GENERAL CONSIDERATIONS

The characteristics of the acute and chronic forms of thrombocytopenic purpura are hemorrhages from the mucous membranes, petechiae or ecchymoses of the skin, a prolonged bleeding time a normal or slightly retarded coagulation a nonretractile clot and a reduced platelet count which seems to be the most important feature of the condition. The nonthrombocytopenic purpura group is manifested by disturbances in the skin, joints and internal viscera, especially the gastrointestinal tract. Morphologically the blood is unchanged from normal, the blood platelets are unchanged.

13 Fred Boerner Jr (A Skin Reaction to Quinine J A M A 68 90, [March 24] 1917) first described the scratch test with quinine sulphate. This author and one of his colleagues showed intolerance to quinine administered orally, manifested by symptoms of erythema and intense itching of the skin. Skin reactions on control individuals were negative. At that time Boerner maintained the positive skin reaction to quinine to be specific and of an allergic nature.

14 Peshkin M M and Fineman A H Asthma in Children VI A Comparative Study of the Scratch and Intradermal Methods of Skin Testing Am J Dis Child 34 815 (Nov.) 1927.

Platelet deficiency in thrombocytopenia was described in 1881 by Brahm,¹⁵ in 1887 by Denys,¹⁶ and in 1895 by Hayem.¹⁷ Similar studies with additional features of the condition have been made by Bensaude and Rivet,¹⁸ Duke,¹⁹ Pratt²⁰ and Minot,²¹ among others. Von Behring²² and Lee and Vincent²³ have observed in thrombocytopenia experimentally produced in animals that the platelets disappeared from the peripheral circulation and tended to clump in the internal organs during anaphylactic shock. It has also been shown that the coagulation time in anaphylactic shock is delayed. Whether this process is comparable to the allergic phenomenon observed in cases of allergic thrombocyto-

penia is not known. Musser and Wintrobe²⁴ state that thrombocytopenic purpura may very rarely occur as part of an anaphylactic reaction. Christian includes anaphylaxis in his classification of purpura as one of the causes of secondary thrombocytopenic purpura.

Sergeant and his associates²⁵ reported a case of proved thrombocytopenia in a young girl in whom blood transfusions, irradiation of the spleen and the administration of various drugs and solution of pituitary brought no improvement. However, the injection of 0.001 Gm of epinephrine hydrochloride daily resulted in a "cure." After the administration of epinephrine hydrochloride the spleen contracted for from six to seven minutes which expresses its blood content, leading to definite hyperglobulia lasting for from twenty to twenty-five minutes. The authors then suggested from these observations that there may possibly be some failure of the suprarenals, forgetting, however that the exciting etiologic factor may have been allergic in nature.

Brinnitzer²⁶ believes that certain relations between anaphylaxis and thrombopenia show that a differentiation of hemorrhagic purpura from the anaphylactoid purpura group is not possible and that probably

anaphylaxis is one of the many factors that etiologically are responsible for the thrombopenic purpura. He reports the case of thrombopenia in a boy, aged 4 years, with blood platelets of 20,000 who developed angioneurotic edema and generalized urticaria ten minutes after receiving a blood transfusion from the mother, whose blood grouping was the same as her child. One month later the blood transfusion was repeated with similar results. This case appears to indicate that the strong anaphylactic reaction to the maternal blood belonging to the same group was due to the anaphylactic feature of the thrombopenic purpura in the child.

COMMENT

Sensitization to drugs inducing various manifestations of allergy has been shown to occur in cases in which such small doses were used as to preclude the possibility of any toxic or even discernible pharmacologic action. Asthma and vasomotor rhinitis have been induced by the inhalation of ipecac,²⁷ rhubarb, lycopodium²⁸ and castor bean,²⁹ and by the ingestion of any of a large list of drugs, including even the synthetic chemicals such as acetylsalicylic acid, phenobarbital, amidopyrine and antipyrine. The other allergic conditions caused by the ingestion of drugs are generalized erythema, urticaria, angioneurotic edema, abdominal colic and eczema.³⁰

It has been generally known that various drugs can cause nonthrombocytopenic purpura and even thrombocytopenic purpura. The patients were regarded as suffering either from an overdose or from the poisonous effect of the drug. It is not generally known that purpura in some of these cases is really due to drug allergy. A case of quinine hypersensitivity causing thrombocytopenia was recently reported by Maritschek and Markowicz.³¹ The patient was a man, aged 35, who had suffered from "quinine intoxication" during treatment for malaria, fifteen years prior to coming under observation. The intoxication at that time manifested itself in purpura and hemorrhages from the mucosae. There remained a persistent hypersensitivity to quinine, so that even small doses (0.3 Gm.) produced severe thrombocytopenia. Sensitization tests were not performed.

Quinine is one of the important and useful drugs employed in therapy. Quinine alkaloid is present in various quinine salts, ranging from 20 per cent in quinine tannate to 81.8 per cent in quinine hydrochloride.³² In the treatment of malaria, Fletcher³³ found that quinidine and cinchonine are quite comparable to quinine in their effects on malarial parasites. If a patient cannot take quinine, one of these dextrorotatory alkaloids can be given and as demonstrated in the case herein reported, without ill effects. This substitution also eliminates the uncertain and dangerous process of hyposensitization to quinine. Dawson and Garbade³⁴

reported positive skin reactions only to the levo isomers of the cinchona group in a patient in whom 0.325 Gm. (5 grains) of quinine sulphate caused symptoms of intense urticaria, alarming dyspnea and abundant nasal discharge. These authors conveniently arranged the various alkaloids of the cinchona group in the accompanying table.

Positive evidences of ergot and quinine allergy caused by ingestion in the same patient inducing symptoms of thrombocytopenia, with positive skin and passive transfer reactions only to quinine (levorotatory) group assumes vast importance, because it carries the inference that drug and other allergenic substances probably enter into the etiology of thrombocytopenia more frequently than the few scattered reports in the literature would indicate.

CYANIDE ANTIDOTES

P. J. HANZLIK, MD

AND

A. P. RICHARDSON, AB
SAN FRANCISCO

Successful chemical antidotes in the treatment of experimental cyanide poisoning are methylene blue, sodium nitrite, triose and sodium thiosulphate. Within limitations, all these agents, except triose, which has not been tried in man, have a demonstrated clinical usefulness. Their actions are both protective and resuscitative. Differing as they do chemically and physically, these agents might also be expected to mediate their antidotal actions differently. This is probably true for simple physical and biologic systems, but in mammals matters appear to be different, and even among different mammals. For instance, in some species (dogs) methylene blue and sodium nitrite are reported to act through the same mechanism which does not seem to be invoked in others (rabbits). Triose and thiosulphate appear to act differently from the dye and nitrite. The newer concepts and apparent complications in these antidotes ought to be understood and explained, if possible, for a proper appreciation and application of the newer treatment of cyanide poisoning.

Interestingly, there have been for many years suggestive data in the literature of pharmacology, which have recently been found valuable for this purpose. Now they are the basis of practical life-saving measures in this desperate poisoning. At the same time there is a large interest in the fundamental action of the novel antidotes for physiologic processes in general. The latter is quite natural, for, in large measure, these agents were originally the means to fundamental considerations of biologic processes, and their practical use in treatment of cyanide poisoning was not even mentioned. A brief summary of the essential historical facts will indicate the development of these various interests.

For instance Heymans and Maigre¹ of Ghent demonstrated in 1921 that methylene blue saved dogs from the cyanide poisoning of malonitrile this being done in connection with

metabolic studies of this dye. Then Sahlén² in 1926 showed that methylene blue possessed an antitoxic action in poisoning from sodium cyanide in mice. However Sahlén feared a possible poisoning action from methylene blue itself, which would preclude its use as a practical antidote. Finally Eddy,³ in 1930, conclusively demonstrated its life saving and respiratory resuscitative actions in dogs, this too being done in connection with fundamental studies of respiration. But in none of these reports was there a definite suggestion of the possible clinical usefulness of methylene blue in cases of cyanide poisoning until Geiger,⁴ in 1932, acting on the advice of one of us,⁵ actually treated with success a clinical case of poisoning and confirmed the experimental results. Since that time several other cases of cyanide poisoning have been successfully treated.⁶

Forty years ago, i.e. in 1893, Heinrich Szigeti⁷ of Budapest demonstrated the presence in living animals of "cyanhematin" which really was cyanmethemoglobin, after injection of cyanide in dogs previously treated with potassium chlorate nitrobenzene, and the like, until their blood was chocolate colored from methemoglobin. He showed that cyanmethemoglobin cannot occur in living animals without first producing methemoglobin. However, it remained for the pharmacologist Enrique Hug⁸ of Rosario, Argentina, to demonstrate the practical usefulness of sodium nitrite in cyanide poisoning. According to Hug its virtue rests on its power to form methemoglobin which it does more effectively than do potassium chlorate and nitrobenzene, originally tried by Szigeti. Hug⁹ has gone further and shown that, in mammals, apparently all methemoglobin formers, among which is included methylene blue act as cyanide antidotes. Thus, the dye and the nitrite would act as antidotes through a common mechanism, which converts the cyanide to the innocuous cyanmethemoglobin. Wendel¹⁰ has expressed a similar view.

The detoxicating action of sugar in cyanide poisoning has long been known, from fascinating tales in fiction to authentic reports in entomology and toxicology. From extensive comparisons of different sugars in this poisoning, Forst¹¹ has shown that only triose or glyceric aldehyde has resuscitative actions after the symptoms of toxicity are developed. The chief basis for the antidotal action of sugars is the direct formation of a nontoxic cyanhydrine although Forst believes that triose is assisted by actions on higher centers. Triose is comparatively poor in mixtures with cyanide in vitro and as a protective for animals while some other simpler sugars excel in these respects. This indicates certain complications which require careful consideration in selecting antidotes for use in the treatment of poisoning. Dihydroxyacetone may be considered in the saccharin category but is not comparable to triose as to efficiency in developed poisoning although it may increase the effectiveness of thiosulphate.¹²

Thiosulphate, of course, has long been recognized as a direct oxidant of cyanide which is converted to the nontoxic sulphocyanate, and is successful as an antidote provided the thiosulphate is injected just before or together with the cyanide. This makes it of little or no practical value in treatment of cases of poisoning. However Hug¹³ and Chen Rose and

Clowes¹⁴ have proposed combining it with other more potent and lasting antidotes such as nitrite, in order to increase the efficacy of the treatment. According to these authors there is a potentiation of antidotal action under these conditions. Colloidal sulphur and sodium tetrathionate belong with thiosulphate, but the former is erratic in action and the latter offers no particular advantage over thiosulphate.

From this brief consideration of the historical background for cyanide antidotes, certain claims and data are worthy of confirmation and correlation. For instance, claims for the efficiency of nitrite, of triose, and of the mixture of nitrite and thiosulphate, and for the unity of the methemoglobin mechanism for methylene blue and nitrite should be verified. Such a discrepancy as the failure of methylene blue and nitrite to act as cyanide antidotes in rabbits, in the face of successes in other mammals and in birds, ought to be clarified, if possible. Otherwise justifiable doubt of the value of these antidotes might persist and confuse attempts at improving the treatment of cyanide poisoning. These questions are considered in this paper, which embodies results on different animals and on blood.

The general purpose was to determine the effects of typical antidotes on blood directly in vitro, on blood after intravenous injection, and on the blood symptoms and outcome of poisoning after surely fatal doses of cyanide. The blood was examined for changes in oxygen capacity and for the presence of methemoglobin chiefly after successful antidotes, but also to some extent after the ineffective agents. The blood changes were compared with the antidotal effects for possible determination of the mechanism of action. The antidotal efficiency was tested in both protective and resuscitative treatments. In the former, the antidote was injected first, and ten minutes later a fatal dose of cyanide, both injections being made intravenously. In the latter type of treatment the cyanide was first injected intramuscularly and then the antidote was injected intravenously, as soon as convulsions were manifested, that is immediately on the development of definite symptoms of poisoning. The dose of sodium cyanide used was 3 mg per kilogram of body weight, which was a surely fatal dose for all animals, whether injected intravenously or intramuscularly. This dose of cyanide caused the typical violent symptoms of poisoning in all untreated animals. Convulsions were definite in from ten to fifteen seconds and death occurred in one minute after intravenous injection, and symptoms occurred in about one minute and death in from two to three minutes after intramuscular injection. The well known symptoms of this poisoning are practically the same for all species and require no description here.

In this work we used 100 pigeons, nine rabbits, seventeen white rats and sixteen guinea-pigs for antidotal tests and bloods from two dogs and three hospital patients besides the bloods of the birds and rodents for examination of chemical changes. At least three animals and three bloods were used for a test with each antidote, and more in the case of the positive antidotes. Pigeons were used for the most part because of economy and convenience, and they served the purpose of our work as readily as would larger mammals such as dogs and cats previously used by others. Rodents were used sufficiently to demonstrate their comparatively inefficient reaction to certain cyanide antidotes.

The oxygen capacity of the blood was determined with a simple device described by Anrep and Harris.¹⁵ Generally 1 cc of blood was used and the error did not exceed 1.5 per cent,

with 2 cc of blood it did not exceed 1 per cent. This simple device deserves to be more generally known both in experimental laboratories and in clinics, since its use would facilitate desirable studies of blood and tissues, in preference to the tedious Van Slyke pipet. Although it is a general practice to rely on changes in oxygen consumption or capacity of red blood corpuscles for evidence of methemoglobin formation, this does not conclusively prove the presence of this blood pigment. For the latter purpose the spectroscopic examination is final, and therefore we made examinations of the same bloods with an Englemann microspectroscope. Unfortunately, however, spectroscopic examination for methemoglobin cannot yield an accuracy greater than 25 per cent, as it cannot be made on whole blood. We used 2 per cent hemolyzed blood in all cases and made comparisons with fresh untreated blood and a blood containing methemoglobin, resulting from nitrite action, in microscopic fields side by side. Many hemolyzed bloods required filtering especially the blood of pigeons, before satisfactory examinations could be made. All results on oxygen capacity were corrected for the effects of the solvent or vehicle used with the antidote, for instance, distilled water or physiologic solution of sodium chloride added to blood or injected into the blood stream reduced the oxygen capacity.

TABLE 1—Positive Cyanide Antidotes Efficiency and Blood Changes in Pigeons

Antidote	Dose per Kg Body Weight	Per Cent Protected*	Per Cent Resuscitated*	Blood Changes		
				Per Cent Reduction in Oxygen Capacity	Met hemo globin (Spec tro scopie)	Number of Fatal Doses of Sodium Cyanide Antagonized

about 25 per cent. Pigeon blood was found to have a normal oxygen capacity of about 95 per cent, rabbit blood 125 per cent, rat blood 123 per cent, guinea-pig blood 109 per cent, dog blood 17 per cent and human blood 18 per cent values which, in general, agreed with those reported in the literature.

The essential results with the positive antidotes are presented in table 1, these being compared with each other in pigeons. The results with other agents are briefly mentioned in the discussion which follows. A correlation of methemoglobin formation and antidotal efficiency of methylene blue and sodium nitrite in cyanide poisoning of different species is presented in table 2. All details are omitted, only the changes are reported.

POSITIVE ANTIDOTES

It is clear from table 1 that sodium nitrite was the most efficient single antidote and that a combination of sodium nitrite and sodium thiosulphate was the most efficient of all antidotal measures tried. Confirmation of Hug¹³ and of Chen, Rose and Clowes¹⁴ in pigeons, nitrite antagonized three fatal doses of cyanide and the nitrite-thiosulphate combination six, i. e., an efficiency ratio of two, while in dogs Hug and Chen, Rose and

Clowes found a ratio of three. Since thiosulphate protected against only one fatal dose of cyanide, there was a potentiation in the mixture, as claimed by Hug and Chen, Rose and Clowes. The antidotal efficiency of these salts was the same in protective and resuscitative treatments.

Methylene blue, as compared with equal doses of sodium nitrite, was only half as efficient, without potentiation in the presence of thiosulphate. A similar tendency was reported by Chen, Rose and Clowes¹⁴. Methylene blue was less successful in resuscitative treatment.

Toluidine blue was somewhat more efficient in protective treatment than methylene blue in equal doses. It was tried because it is more positive than methylene blue on the oxidation-reduction scale for reversible systems, and the result obtained sustained an expectation of greater efficiency, but more extensive data would be needed to prove this point.

Triose was somewhat more efficient than methylene blue, but the dosage was nearly eight times greater, although it was less efficient than sodium nitrite. It acted equally well in protective and resuscitative treatments but by itself produced rather marked physiologic disturbances—especially increased respiration and restlessness—whereas all the other antidotes appeared to be symptomless.

Crystalline dog methemoglobin antagonized only one fatal dose of cyanide but was equally effective in protective and resuscitative treatments. The dose of 0.5 Gm per kilogram used approximated the content of methemoglobin in blood, as indicated by reduced oxygen capacity after nitrite and methylene blue. However, the injected methemoglobin solution was quite rapidly excreted in urine, which probably explained its lower antidotal efficiency as compared with the higher efficiency of methemoglobin of corpuscles after injection of nitrite.

When the reduction in oxygen capacity of the blood was used as evidence of methemoglobin, there was clearly a division between the antidotes. Methemoglobin formers were methylene blue, toluidine blue, sodium nitrite, nitrite-thiosulphate combination and crystalline methemoglobin. However, only the nitrite alone showed the presence of methemoglobin spectroscopically. The other agents did not because not enough methemoglobin was present for identification. The decrease in oxygen capacity was not proportional to antidotal efficiency of the different agents. For instance, the nitrite-thiosulphate combination and nitrite had the same effect on oxygen capacity, but the former was once again as efficient against cyanide, toluidine blue had a greater antidotal efficiency than methylene blue but was only slightly more depressant on oxygen capacity, triose and thiosulphate were of about the same order of antidotal efficiency as the dyes but did not cause blood changes. Therefore the mechanisms of the antidotal actions of triose and thiosulphate, at least, were different from those of the dyes and nitrite. The sugar reacted with the cyanide to form cyanhydrin, and the thiosulphate oxidized it to sulphocyanate, both products being non-toxic. Since the sugar and the thiosulphate were less efficient than the dyes and nitrite, there was no doubt of the very high combining efficiency of methemoglobin for cyanide. A correlation of decreased oxygen capacity

and antidotal efficiency for methylene blue and nitrite will be discussed farther on

The time element was important in the antidotal efficiency of both methylene blue and sodium nitrite. The optimum time under the conditions of cyanide poisoning in our experiments was ten minutes for protection and blood changes. No decline in efficiency was noticeable at the end of fifteen minutes, but at the end of half an hour the reduced oxygen capacity of the blood was about one half that at the end of ten minutes, and the majority of animals died from the cyanide. One hour after injection of the methylene blue or nitrite the blood was practically back to normal and no animals could be saved. This rapid decline in efficiency with time was due partly to a rather rapid reconversion of the methemoglobin to oxyhemoglobin and partly to urinary excretion of methemoglobin. In pigeons, the rapid urinary excretion of injected methemoglobin was quite noticeable, the expelled urine at the end of from ten to fifteen minutes being a deep chocolate brown.

Added to bloods in vitro, the various agents caused effects identical with those after injection. Under these conditions it was clear that the dyes were extremely

and possibly even nitrite and nitrite-thiosulphate, although the predominant mechanism rests with methemoglobin.

NEGATIVE ANTIDOTES

Negative, inefficient or extremely variable agents tried in cyanide poisoning were Dyes ethylene blue (up to 40 mg per kilogram) and dinitrophenol (6 to 7 mg per kilogram, with pyrexia). Methemoglobinizers pyrogalllic acid (10 to 20 mg per kilogram, inefficient), chlorate (0.5 Gm per kilogram), acetanilid (4 Gm per kilogram) and amyl nitrite (inhalation, inefficient). Anticonvulsants barbitol (0.2 Gm per kilogram) and ether (inhalation). Oxidants dinitrophenol and crystalline dog oxyhemoglobin (0.5 Gm per kilogram).

Very interesting were the negative results with the two dyes ethylene blue and dinitrophenol. The results appear fundamentally significant. Ethylene blue is, of course, as close chemically to methylene blue as anything that might be conceived, yet the ethyl group in this dye cannot exert the blood and physiologic changes necessary for detoxication of cyanide. This dye did not affect the oxygen capacity of blood in vitro and in vivo and formed no methemoglobin. Therefore the methyl group of methylene blue is responsible for these changes. Dinitrophenol greatly increases the oxygen consumption of tissues and stimulates oxidative metabolism, but it does not affect the oxygen capacity of blood in vitro and in vivo or form methemoglobin, even after concentrations and doses that would prove ultimately fatal. Therefore the detoxication of cyanide, according to this evidence, would not be a concern of cellular metabolism, tissue oxidation or fundamental respiratory mechanism, but rather of methemoglobinemia. Conceivably, however, dinitrophenol may activate only some phase of cellular metabolism or oxidation, which is ineffective for oxidizing cyanogen. Finally there are reasons to believe that methylene blue also can activate fundamental respiratory and oxidative processes, as already referred to, and this dye is a good antidote for cyanide. The question becomes too involved with hypothetical mechanisms for profitable discussion, but it is believed that further study of these dyes is bound to throw additional light on the fundamental nature of metabolic processes.

Of the remaining negative agents, chlorate and acetanilid were too slow or imperfect as methemoglobin formers, no decrease in oxygen capacity of the blood after these agents was demonstrable. In less than toxic doses, pyrogalllic acid was inefficient. Inhalation of amyl nitrite¹⁷ proved unsatisfactory under our conditions. Barbitol and ether, in definitely depressant quantities, proved futile and disproved a theory of possible anticonvulsant effects of central depression resulting from any cause, including the low blood pressure of nitrites. The inefficiency of crystalline oxyhemoglobin showed that the protective effects of methemoglobin were of a chemical nature and not physical or colloidal.

VAGARIES AND CORRELATIONS OF METHYLENE BLUE AND SODIUM NITRITE

Negative results also were obtained with methylene blue and sodium nitrite in rabbits. This was due to a comparative absence of methemoglobin, since there was only about 2 per cent reduction in oxygen capacity of the blood. The complement to this result was the complete protection of two rabbits that received intravenously single fatal doses of sodium cyanide five minutes after intravenous injection of crystalline methemoglobin, 0.5 Gm per kilogram. Two other rabbits, which received the cyanide ten minutes after the methemoglobin were not saved, owing presumably to the rapid escape of this pigment from the circulation. Consequently, claims of positive results with a methemoglobinizing agent, such as methylene blue in cyanogen poisoning of rabbits, and treatments based on such results must be regarded with skepticism. The use of rodents, especially the rabbits was probably partly responsible for the negative results of Trautman,¹⁸ who tested the value of methylene blue in poisoning from inhalation of hydrocyanic acid vapor.

Clearly the rabbit is not suited for testing the antidotal efficiency of methylene blue or nitrites or for investigating

TABLE 2—Correlation of Percentage of Reduction in Oxygen Capacity of Blood (Methemoglobin Formation) with Antidotal Efficiency of Methylene Blue and Sodium Nitrite in Cyanide Poisoning of Different Species

	Methylene Blue		Sodium Nitrite	
	Per Cent Reduction in Oxygen Capacity	Number of Fatal Doses of Sodium Cyanide	Per Cent Reduction in Oxygen Capacity	Number of Fatal Doses of Sodium Cyanide
Dogs	16.0	2	24.0	4
Pigeons	10.0	1½	20.0	3
Rats	6.8	1	10.7	2
Guinea pigs	4.8	1	8.6	1
Rabbits	2.0	0	2.5	0

Estimates for dogs were based on data from Hug (Rev. Soc. Argent. Biol. 9: 461, 1933) and Chen, Rose and Clowes (Proc. Soc. Exper. Biol. & Med. 31: 2.0 (Nov. 1933)). One fatal dose of sodium cyanide 3 mg per kilogram intravenously or intramuscularly; doses of methylene blue and sodium nitrite each 20 mg per kilogram intravenously.

inefficient methemoglobinizers as compared with the nitrite. The dyes required several days for such catalytic action when concentrations approaching those of injections were used. This inefficiency in vitro, taken together with a low methemoglobinizing efficiency in vivo, but a high antidotal efficiency in practice, especially in clinical cases, suggests that cyanmethemoglobin is not the sole life-saving factor. After all, the seat of cyanide poisoning is in the tissues and not in the blood, and methylene blue is effective even after symptoms of tissue poisoning (convulsions, respiratory stimulation, and the like) are manifested, regardless of how the nitrite would act. This naturally raises questions of possible direct tissue and cell actions of the dye. Conceivable is a catalyzing action on respiration, or on respiratory ferments, or an action of the dye itself as respiratory catalyst. Either one of these mechanisms could preserve life and assist in overcoming the poison, meantime, natural detoxicating actions of the tissues on the cyanide would be taking place. The two actions combined would be greater than either one alone. Something of the sort might also be imagined as the basis of potentiation by sodium thiosulphate, which forms no methemoglobin whatever. Therefore, this leaves something yet to be discovered which might fully explain the actions of methylene blue and toluidine blue,

17 Chen K. K., Rose C. L. and Clowes G. H. A. Amyl Nitrite and Cyanide Poisoning. J. A. M. A. 100: 1920 (June 17) 1933.
18 Trautman J. A. Pub. Health Rep. 48: 1443 (Dec. 1) 1933.

methemoglobin That such life tests with these rodents are inconclusive and misleading was pointed out several years ago by Heubner¹⁹ in his criticism of the studies of methemoglobin formation from aniline, ferricyanide, nitrobenzene and nitrite by Van Slyke and Vollmund²⁰ who used horse and rabbit bloods, and of aniline poisoning by Young, Muehlberger and Meek,²¹ and of acetanilid poisoning by Young and Wilson,²² who examined rabbit blood. In fact, it was recognized forty years ago by Szigeti⁷ that the blood of carnivora was better suited to methemoglobin production than that of herbivora, but this fact has been ignored by many investigators up to the present day. Therefore the inadvisability of such tests with horse and rabbit bloods, which are not uncommonly employed in biochemical and physiologic experimentation, cannot be too strongly emphasized in order to avoid confusion when it comes to transferring results to cases of human poisoning.

However, not all rodents are to be regarded in the same class with rabbits, for we could demonstrate protection against fatal doses of sodium cyanide in rats and guinea-pigs receiving methylene blue and sodium nitrite. Simultaneously, the bloods of these rats and guinea-pigs showed reduced oxygen capacity and, after nitrite, also occasionally spectroscopic suggestion of methemoglobin. In fact, the data on antidotal efficiency, as indicated by the number of fatal doses of cyanide antagonized, and on reduction in oxygen capacity of the blood in different species, emphasize a close correlation of antidotal efficiency of the dye and nitrite with methemoglobin formation. Such data are presented in table 2, the data on dogs being obtained from recent literature and those on other animals from our experiments. According to table 2, the greater the percentage of reduction in oxygen capacity of the blood (methemoglobin) the greater is the number of fatal doses of cyanide antagonized. Gram for gram, sodium nitrite tends to be nearly once again as efficient as methylene blue in reducing oxygen capacity and antagonizing cyanide. Roughly, about 5 per cent reduction in oxygen capacity appears to be enough to antagonize one fatal dose of cyanide (guinea-pigs), 10 per cent reduction can antagonize from one and one half to two fatal doses (pigeons and rats), from 16 to 20 per cent, two to three fatal doses, and about 25 per cent, four fatal doses. Dogs respond most efficiently to both dye and nitrite as to reduction of oxygen capacity and efficiency against cyanide, pigeons somewhat less, rats and guinea-pigs still less, and rabbits least or not at all. The decrease in species reactivity to both antidotes is graduated according to decreases in oxygen capacity of their bloods, being especially noteworthy with nitrite. Man probably reacts similarly to omnivora, although our data were too limited and the doses of methylene blue and nitrite were not comparable with those in table 2. For instance, 10 mg per kilogram intravenously of methylene blue in an adult man reduced the oxygen capacity of the blood 11.9 per cent in ten minutes, and this recovered to 6.1 per cent in one hour, 5 mg of sodium nitrite per kilogram intravenously in another man reduced the oxygen capacity 6 per cent in ten minutes and there was a considerable fall of blood pressure, flushing of the skin and respiratory excitation.

Perhaps the differences between rodents and other species and between rodents themselves are related to dietary and metabolic differences. At least, omnivora (dogs, pigeons, rats) and carnivora (dogs, cats) respond very positively with these antidotes, while herbivora do so less effectively (guinea-pigs) or not at all (rabbits). Clearly, the greater the methemoglobinemia whether as the result of an antidote or according to animal species, the greater is the resistance to cyanide poisoning. Therefore, when biologic tests for methemoglobin formation are necessary in cases of poisoning, or in researches, the choice animals are dogs (cats, according to Heubner) or birds possibly also frogs for nitrite. Species peculiarity as to methemoglobin formation is apparently not related to normal oxygen capacity of the blood, for, in this regard, carnivora and birds

are farther apart than are carnivora and rodents. It might be related to corpuscle permeability. The use of hemolyzed blood in such tests would be something different from whole blood, as would also tests *in vitro* from those *in vivo*.

CHOICE OF ANTIDOTE AND DIRECTIONS FOR TREATMENT IN CYANIDE POISONING

From the results and questions that have been discussed, the first choice and an alternative choice of systemic antidotes in treating cyanide poisoning can be indicated. Although sodium nitrite and the nitrite thiosulphate combination are more efficient in animals than is methylene blue, other considerations indicate the desirability of choosing methylene blue, for human cases. The chief danger from nitrite is sustained circulatory collapse, which might be invoked before symptoms of poisoning have advanced to the danger point or be added to impending or existing shock. The marked methemoglobin formation that nitrite causes could hardly be anything but an added unfavorable influence in case of collapse. These undesirable effects would be expected from doses of from 10 to 20 mg per kilogram, which would give total intravenous doses of from 0.7 to 1.4 Gm for an adult of 70 Kg (140 pounds) body weight. Mota²³ injected a total dose of 0.57 Gm sodium nitrite intravenously in a human case of cyanide poisoning with recovery. It may be argued that the patient could be given the benefit of the doubt on the supposition that nitrite collapse could not be worse than cyanide poisoning. As for using thiosulphate together with the nitrite, this would not avoid nitrite shock. As a matter of fact the intravenous injection of a large volume of thiosulphate solution, in addition to the nitrite, should not be lightly undertaken. Furthermore, it is probable that thiosulphate as a stock antidote would give more trouble than value, for thiosulphate decomposes in moist air and in solution. The salt would have to be kept dry and the solution made fresh. Thus the time consumed would tend to defeat a possible potentiating action on the nitrite, and under such conditions the nitrite might as well be tried alone. Moreover, the effective dosage of thiosulphate used in animals would be prohibitive in man, that is, quantities from 70 to 105 Gm, or more than 2 to 3 ounces, total. Less than this is hardly worth while trying.

On the other hand, methylene blue keeps well in aqueous solution or in 1.8 per cent (isotonic) sodium sulphate solution. It should not be dissolved in physiologic solution of sodium chloride, since precipitation occurs, owing to a common ion (chloride) action. Its antidotal efficiency in cyanide poisoning is after all fairly high, and its clinical usefulness has been demonstrated. The antidotal action is assisted by preservation of all important physiologic functions practically unimpaired. Its toxicity is less than that of nitrite and it forms less methemoglobin, all of which accrues to physiologic recovery from poisoning. Doses of from 10 to 20 mg per kilogram would be the equivalent of from 0.7 to 1.4 Gm for a 70 Kg adult and actually Dr Guger has injected 2 Gm (200 cc of 1 per cent) intravenously with life-saving effects in cyanide poisoning. Triosulphate causes such vigorous excitation of respiration and restlessness that it cannot be advised at present. Thiosulphate alone is, of course, practically inefficient. Therefore this leaves methylene blue as the antidote of first choice, and sodium nitrite with or without thiosulphate, as the alternative, or second choice. In prac-

²³ Mota Rev. med. del Posario **23**: 2 (Aug.) 1933 (with discussion by Hung).

tice, the treatment as proposed for and actually used in the emergency hospitals of San Francisco is as follows

Inject immediately 50 cc of a 1 per cent solution of methylene blue (containing 18 per cent of sodium sulphate) intravenously, repeat, if necessary, until a total of 200 cc is injected. Frequently, consciousness and reflexes are restored before the first 50 cc is completely injected, but, if the patient lapses into unconsciousness, or manifests respiratory depression, resume the methylene blue treatment. As quickly as possible proceed with gastric lavage, using 5 per cent sodium thiosulphate. This oxidizes any unabsorbed poison. Artificial respiration, or oxygen carbon dioxide inhalation is given if necessary, or as needed for the cyanosis and effemine or digitan hypodermically, or strophanthin intravenously, for circulatory and respiratory stimulation.

The alternative procedure from the beginning is a slow and careful intravenous injection of 1 per cent sodium nitrite solution, in five divided injections, until 50 cc is injected in about one hour. If improvement is manifested but prognosis is still unfavorable, the injection may be cautiously continued, but it is to be stopped at once in case of sudden collapse. Epinephrine should be ready at hand to combat nitrite shock, if necessary. Fortify the nitrite treatment at once with the intravenous injection of 20 cc of freshly prepared 5 per cent aqueous solution of sodium thiosulphate (filtered), and, if necessary, continue the injection up to a total of 500 cc if possible. The remainder of the treatment is the same as the foregoing.

The solutions used in these treatments can be readily sterilized by boiling for fifteen minutes.

It should be kept in mind that clinical cyanide poisoning is not always as rapidly fatal as may be imagined from animal experiments or textbook statements. There is generally considerable cyanosis in man, and symptoms or unconsciousness may be present for two or three hours, which ordinarily will be ample time for administering the treatments suggested. In suicidal poisoning, the cyanide is usually swallowed, which requires giving the whole treatment. Accidental poisoning, in different degrees, is quite common in ports where fumigation of ships with hydrocyanic acid is a routine procedure, and in fruit growing regions where hydrocyanic acid is used on a large scale as an insecticide, as in California. Emergency kits, therefore, should be properly equipped with the newer antidotes.

CONCLUSIONS

1 Experimentally effective in protective and resuscitative treatments of fatal cyanide poisoning, and clinically useful, in order of decreasing efficiency, are a combination of sodium nitrite and sodium thiosulphate, sodium nitrite, methylene blue and sodium thiosulphate. Experimentally effective, but clinically inadvisable, is triose (glyceric aldehyde).

2 In mammals, including probably man, the antidotal actions in cyanide poisoning of the following are mediated predominantly through methemoglobin formation: nitrite-thiosulphate combination, nitrite, methylene blue and toluidine blue. Triose apparently forms cyanhydrine and is assisted by central stimulant actions. Thiosulphate is a direct oxidant of cyanide with formation of sulphocyanate.

3 Some kind of direct action, in part at least, on mammalian tissues and cells, independently of methemoglobin, is postulated for methylene blue, and such action is predominant in antagonizing cyanide poisoning of simple physical and biologic systems.

4 The most interesting of a number of ineffective agents are ethylene blue which is chemically close to methylene blue, and dimetrophenol, a powerful meta-

bolic stimulant and oxidant. Their ineffectiveness clearly indicates the specificity of methylene blue, the high combining chemical efficiency of methemoglobin, and the subordinate importance of tissue oxidation, at least as activated by dimetrophenol.

5 Life tests for methemoglobin formation in certain species of animals are useless. There are procedures for and limitations of blood examinations, which are valuable in interpreting and transferring results to human cases of poisoning.

6 The choice of antidotes and directions for treatment in cases of cyanide poisoning are outlined in this paper.

SYMPTOMS OF VIOSTEROL OVERDOSAGE IN HUMAN SUBJECTS

C. I. REED, PH.D.
CHICAGO

During the past five years there have been carried out in the department of physiology in the University of Illinois College of Medicine a number of fundamental investigations on the physiologic mechanisms involved in the action of vitamin D. The information derived from these and other investigations has suggested the therapeutic use of this substance in concentrated form in a number of clinical conditions. However, it is my purpose in this paper not to discuss the results of these investigations but to describe some of the results of overdosage. Consequently, the clinical results of overdosage will be discussed without particular regard to the conditions for which the administration was undertaken. A. F. Hess and Lewis,¹ Bamberger and Spranger,² Opitz,³ and J. H. Hess, Poncher, Dale and Klein⁴ have all described toxic conditions in children, and Laurens⁵ has reviewed the literature on toxicity in experimental animals due to irradiated ergosterol in some form. But there have been no extensive detailed accounts of this condition in adult human subjects, except those of Crimm.⁶

Much has been written and more implied about the danger from excessive amounts of activated ergosterol or viosterol. That it is an extremely potent substance is apparent. However, this fact does not militate against its use as a therapeutic agent if proper precautions are observed.

The first clinical use of viosterol was naturally in the condition resulting from vitamin D deficiency, namely, rickets. The cardinal manifestation of this condition is a disturbance of the metabolism of calcium and phosphorus. The predominant response to the administration of viosterol in this condition, then, is

From the Department of Physiology, University of Illinois College of Medicine.

The expenses of these investigations have been borne in part by grants from Mead Johnson and Company from the American Academy of Arts and Sciences and from the Committees on Scientific Investigation and on Therapeutic Research of the American Medical Association.

a correction of this dysfunction. For this reason, viosterol came to be characterized as the "calcium-raising" factor. Attention was focused on this action and for some years little attention was paid to possible effects on other physiologic mechanisms. Overdosage effects have been thus quite generally associated with hypercalcemia.

The various projects undertaken here have clearly shown that the danger of excessive dosage is not serious and that toxic effects are only incidentally associated with hypercalcemia. Or, perhaps, a more correct statement would be that in human subjects there are other more reliable signs of toxicity than hypercalcemia.

In an earlier publication⁷ it was shown that intravenous injections of concentrated viosterol in normal dogs may sometimes lead to extreme toxicity and death in a few days without consistent change in blood calcium. Also, severe symptoms of toxicity have been produced in human subjects without any elevation of blood calcium or phosphorus concentrations.⁸ On the other hand, in both normal dogs and human subjects, hypercalcemia of great magnitude has been produced and maintained for days without evidence of toxicity.

While it is probable that the two conditions—toxicity and hypercalcemia—occur together very frequently, there are enough exceptions to make it clear that they are not interdependent but merely concurrent. With the administration of parathyroid extract it is seldom possible to elevate the blood calcium of dogs above 16 mg per hundred cubic centimeters without danger, while with viosterol we have been able to sustain a hypercalcemia of 29 mg for two weeks without even loss of weight. In one young adult human subject, a hypercalcemia of 24 mg was sustained for eight days without evidence of intoxication. This subject has been observed for two years since, with no indication of subsequent injury.

That excessive calcium deposition in soft tissues may occur even with relatively low dosages of viosterol has been shown in this laboratory⁹ and elsewhere. This has led to considerable apprehension. That this is not justified may be shown by the following observation.

If normal animals to which large doses have been administered until definite symptoms of toxicity have appeared are killed at any time during the period when calcium elimination in the urine is high and the tissues are examined, it will be found that many organs contain calcium deposits, microscopic examination will show that in many tissues, particularly the kidneys, cellular injury has occurred.

If, however, dogs in a comparable state of toxicity are allowed to survive until urine calcium elimination is again normal and until weight losses are recovered, no such deposits of calcium will be found in the soft tissues, and cellular injuries will have been repaired.

Furthermore, the toxicity in man may be recognized very early, even by the subjects themselves, before any serious damage has occurred. The indication, in such cases, is for discontinuance of viosterol until these symptoms disappear. Except under unusual conditions, it is then possible to resume administration at a lower dosage and still secure therapeutic results. Apparently

such subjects become tolerant in certain respects after a rest period.

Viosterol 10,000 X has been administered to more than 300 human subjects during the past three years for a variety of purposes. Of this number, 230 had hay fever and asthma, fourteen had postoperative parathyroid tetany, and the remainder, including several apparently normal subjects, comprised a group with a variety of conditions. With the highly potent preparation it was not difficult to induce early symptoms of overdosage. From these cases it has been possible to secure accurate information as to the onset of symptoms of overdosage, the symptom complex of which is fairly uniform in course and outcome.

This preparation is approximately 100 times as potent as the standard preparation available on the market. It contains 920,000 international units of vitamin D per cubic centimeter. The average of a large number of determinations was 30 ± 2 drops per cubic centimeter of this particular concentration. Since most of the quantitative administration has been by drops, it is convenient to note that 1 drop contains approximately 30,000 international units whereas 1 drop of the 250 D (100 X) preparation would contain about 300 international units.

It is a question whether the doses we have given in many cases bear any relation to the normal physiologic action of vitamin D. There is not enough evidence at present to settle this question. Although very much smaller doses are sufficient to correct the physiologic disturbances in vitamin D deficiency, there is some evidence which suggests that the effects of even these high doses are physiologic.

The therapeutic effect sought will determine the dosage to be administered in a given condition. For various conditions we have administered daily as high as 3 cc of viosterol 10,000 X to human subjects—in one case for a period of five days without the slightest evidence of injury. However, in a few cases as little as 4 drops daily for three days produced symptoms of gastrointestinal disturbance. Several of these patients have been found to be sensitive to corn protein. It will be recalled that viosterol is a solution of irradiated ergosterol in corn oil. From this it appears that the symptoms were not due to hypervitaminosis D *per se* but to the allergic response to the protein contained in corn oil.

In a woman, aged 40, 15 drops daily for ten days has on three successive occasions produced nausea on the eleventh day. Corn oil alone did not cause this result. Obviously this represents a toxic threshold for this particular subject that is not due to allergy.

The most common initial symptom of incipient toxicity is increased frequency of urination. Most patients do not appear to experience any particular urethral irritation, and there does not appear to be any pronounced polyuria. In dogs, however, polyuria is rather common. The reason for this frequency is not clear. At first it appeared to be always associated with increased urinary calcium elimination. However, it has since been found that it occurs independently.

Concurrently with this symptom in many cases, or following its appearance, there also occurs anorexia with persistent nausea. This has occurred in every case of overdosage. In the earlier investigations the significance of this symptom was not recognized because certain subjects neglected to report the occurrence of nausea.

⁹ Reed C I, Dillman L M, Thacker E A and Klein R I. The Calcification of Tissues by Excessive Doses of Irradiated Ergosterol. *J Nutrition* 6: 371 (July) 1933.

Following quickly on the stage of nausea there was usually a gastro-intestinal disturbance easily confused with a generalized gastro-intestinal infection, except that there was never any significant elevation of temperature. Vomiting and diarrhea were usually quite severe but always abated within three to four days after the dose was reduced or the treatment discontinued.

While most subjects tend to gain weight on a dose of from 4 to 6 drops daily, every one showing definite symptoms of toxicity lost weight, in two cases as much as 20 pounds (9 Kg). In an investigation of the effects of viosterol on oxygen consumption in normal dogs¹⁰ and rats,¹¹ it was noted that whenever weight loss occurred there was always an increase in oxygen consumption. While no determinations of metabolic rate were made in any of our human subjects, it seems probable that there was an increase in metabolic rate along with loss of body weight. Poncher and Gasul¹² have suggested the same thing in connection with a study of viosterol therapy in tuberculous children.

This increase in metabolic rate is associated with an increase in the urinary excretion of nitrogen.¹⁰ It appears that the thyroid mechanism must be affected by the excessive viosterol therapy.

Other symptoms that have been noted more or less commonly are muscular weakness, lassitude, dull aching in the muscles, dizziness, disturbed muscular coordination and disturbed equilibrium.

Despite a rather widespread impression that viosterol exerts an aphrodisiac effect, careful questioning of fifty men, forty-three of whom were married, as to subjective libido, frequency of intercourse and general interest in sex life has failed to bring out any evidence of aphrodisia other than that associated with general improvement in health. The maximum doses in this group ranged from 10 to 60 drops over periods of from one month to three years.

A similar group of women ranging in age from 20 to 60, all married, were questioned, and of this group only one admitted any stimulation of libido. Since this woman was given corn oil alone for a period of two weeks during which she first reported this stimulation, it is apparent that the viosterol was not responsible.

The work of Dodds and his collaborators¹³ indicates that the sterols constitute a large group of chemically related substances, some of which are estrogenic to experimental animals. This suggested an investigation of the possibility that viosterol might exert such an influence on human subjects. A carefully prepared questionnaire was circulated among ninety female subjects ranging in age from 13 to 58 years, all of whom were menstruating regularly. The data requested included information as to the age of onset, regularity, frequency and duration. The doses ranged from 8 to 75 drops. The period of administration ranged from two weeks to six months.

One young unmarried woman who received a dose ranging from 20 to 60 drops daily over a period of two and one-half months stated that the frequency of menstruation was exactly doubled during that period and promptly returned to normal on discontinuance of the treatment.

One other subject, a widow aged 35, stated that during a period of three months of viosterol administration, in doses ranging from 6 to 40 drops, the menses appeared six days early in each cycle and that for two cycles after discontinuance of administration there was a delay of five days each time. Subsequently there was no disturbance.

In another instance a married woman, aged 47, stated that about ten days after cessation of normal flow at the first cycle after the beginning of administration of viosterol (two weeks previously) there began a scanty flow which lasted about ten days and then ceased. The treatment was continued for another six months, during which time there were no further irregularities. At the time of this irregularity she was receiving 15 drops daily. Subsequently the dose was increased to 40 drops a day for seven days.

Two other women reported definite shortening of the intermenstrual period on doses of 20 and 25 drops, respectively.

In three other instances there were complaints of slight disturbances, which, however, never became serious enough to cause any great discomfort. The doses were from 15 to 20 drops. While it is possible and even probable that all these effects did depend on the viosterol administration, it is evident that the disturbances are not of serious consequence, since there are only eight such cases in the group of ninety, and only one of these experienced any pronounced increase in subjective discomfort.

There has been some apprehension that continued heavy dosage of viosterol will lead to arteriosclerosis. A recent publication by Appelrot¹⁴ indicates that, in dogs, a hypertension occurs, associated with a thickening of the media of the blood vessels. There is a practical criticism that may be made of his work, namely, that the method of measurement of blood pressure employed is not reliable.

Viosterol 10,000 X has been administered to twenty-three subjects 50 years of age or over. One of these was a woman, aged 72, who ingested 20 drops, or 600,000 international units, daily over a period of four months. At the beginning the blood pressure was 152 systolic, 108 diastolic. At the end of that time the reading was 145 systolic, 88 diastolic. Subsequent observation during a period of one month without treatment did not show any significant change, the reading now being 145 systolic, 92 diastolic. While none of these changes are of a magnitude that would be of much significance, there appears to be slight improvement, if anything.

Another subject, a woman, began to take 0.5 cc of viosterol 10,000 X daily over three years ago for relief from postoperative tetany. After two months this was reduced to 20 drops a week. She was then 63 years old. Her blood pressure was 158 systolic, 97 diastolic, average of four readings. In January 1934 the reading was 160 systolic, 100 diastolic, a change of no significance. In none of the other subjects has there been any evidence that the treatment has in any way affected the state of resilience of the blood vessels.

That calcification or medial fibrosis may produce hypertension is recognized. That viosterol in sufficiently high dosage may produce one or the other of these conditions is possible. The amount necessary to produce either condition in the human subject has never

¹⁴ Appelrot Samuel. Hypertension D and Blood Pressure in Dogs. *Am. J. Physiol.* 105: 294 (Aug.) 1933.

been determined. If conclusions may be drawn from results in dogs, there has never yet been given to any human subject enough viosterol to produce either calcification or medial fibrosis within the periods of time reported.

In four men ranging in age from 50 to 60 years there developed within a week after administration of from 10 to 20 drops daily very severe and persistent constipation, which disappeared after from two to three weeks. During this period, however, it was necessary to resort to frequent enemas.

It would appear, then, that there need be little apprehension about the administration of amounts ranging up to 150,000 international units daily for indefinite periods. Larger amounts had better be limited to periods of a few months at most, depending on the therapeutic effects desired.

The treatment of the condition of overdosage has in our work been limited entirely to decreasing the dose or discontinuing the treatment. Crumm⁶ has suggested the intravenous injection of sodium bicarbonate or Ringer solution. We have not investigated either procedure.

SUMMARY

A study has been made of the administration of highly concentrated viosterol to 300 human subjects ranging in age from 7 to 72 years. The doses ranged from 3,000 to 2,760,000 international units daily, or a maximum of 920 times the normal antirachitic dose of 3,000 international units. Of these, forty-three patients showed symptoms of toxicity in varying degrees.

1853 West Polk Street

THE INCIDENCE AND TREATMENT OF TRICHOMONAS VAGINALIS IN PREGNANCY

OSCAR GLASSMAN, M.D.

NEW YORK

Little attention is given to the vaginal secretion of pregnancy. Though normally greater in amount than in the nonpregnant, it is often considerably increased, contains leukocytes and pathogenic micro-organisms, and results in definite symptoms of varying intensity. The latter condition is frequently dismissed as a normal physiologic change, whereas if the secretion is examined microscopically it will be found in a great majority of instances to be associated with *Trichomonas vaginalis*.

This flagellate is found in about 10 to 40 per cent of pregnant patients and may be found in from 50 to 70 per cent of all patients with leukorrhea. It probably occurs more frequently in the pregnant than in the nonpregnant. One of the reasons may be that the increased female sex hormone in the body enhances its growth. Stein¹ has shown that female sex hormone added to a culture medium causes a much more rapid growth of the parasites and suggests that the marked recurrence of the organism following the menses may be due to the female sex hormone in the menstrual blood and not to the blood itself.

In a series of 309 unselected pregnant patients personally examined at the Berwind Maternity Clinic, trichomonas was found in the vaginal secretion in 20.7

per cent. Seitz² found the parasite in 20 per cent of pregnant patients, Brumpt³ in 10 per cent of gynecologic patients, Hoehne⁴ in 28 per cent nongravid as against 34 per cent of 102 gravid patients, Vavilova⁵ in 28 and 35 per cent, respectively, of pregnant and nonpregnant women, Liss⁶ in 405 pregnant women, observed the organism in 19.5 per cent and Traugott⁷ in 125 pregnant women, in 21.6 per cent, while Hausmann⁸ in 200 unselected gravid patients reported 37 per cent infected as against three in 150 cases examined by Davis⁹. Bland¹⁰ found an incidence of 23.6 per cent in 500 obstetric patients. Of these, 257 were Negroes and 243 were white. Of seventy-nine patients with *Trichomonas vaginalis* in our clinic, forty-five or 57 per cent were Negroes. There apparently is a greater incidence in Negro than in white women.

Several authors report an increased puerperal morbidity in cases presenting trichomonas infection. Bland and his associates report a puerperal morbidity rate of 50 per cent in patients with the parasite and 25.4 per cent in those without. The morbidity was higher in white than in the Negro patients. Schmid and Kamnicker¹¹ show a morbidity of 10.3 per cent in cases with trichomonas as against 4.8 per cent without trichomonas, and Liss, 29 and 15.3 per cent, respectively. Gragert¹² has 29.1 per cent morbidity. After antenatal treatment his morbidity rate dropped to 7.7 per cent. When the cases were positive for trichomonas in spite of treatment, the rate was 11.3 per cent. Cornell¹³, Greenhill¹⁴ and others state that the trichomonas did not influence the lying-in period in their cases. We found no increase in puerperal morbidity in our series.

There is still a controversy as to the pathogenicity of this parasite. Donne¹⁵ (1836) in the first report associated it with venereal disease. The various views at present are that it is harmless, that the purulent discharge is a result of specific bacterial infection and the trichomonas is a secondary invader, that the primary pathogen is yeast and the trichomonas occurs symbiotically as a nonpathogenic parasite, and that it is a specific infection. Most observers here and abroad, however, agree that with the eradication of this flagellate the associated symptoms and leukorrhea disappear.

The life history of the trichomonas is not known. It can be obtained in cultures and it reproduces by longitudinal binary fission. No cyst forms have been described, except possibly by Bensen¹⁶ but there is apparently a focus from which reinfection occurs. The parasite has been found in the rectum, mouth and bladder as well as in the vagina. One case of pyelitis due to this organism has been reported, as well as a number of cases of urethritis and prostatitis. In a few of the latter, the wives had a trichomonas vaginitis. It has also been found in the vagina of the monkey, in the

mouth of the cat and in the intestine of the monkey, opossum and prairie dog,¹⁷ as well as in other animals.¹⁸

Trichomonas hominis, which is found in the stools, is very similar to *Trichomonas vaginalis* except in the length of the undulating membrane. Stein has shown that under varying conditions the size and shape of the parasite and the length of the membrane can change. The proximity of the rectum to the vagina and the habit of most women of cleansing the anus toward the vagina after each defecation would allow of easy access from the intestine if this should be the focus. The bladder has been mentioned as a focus for reinfection, but the trichomonas would undoubtedly have been observed in routine examination of the urine and would have aroused considerable study long before the present interest.

The symptoms are essentially the same as found in nonpregnant patients, notably profuse discharge, which may be foul itching and burning about the vulva and introitus, dyspareunia, and sometimes urinary symptoms. In mild cases the symptoms can be elicited only on close questioning, as they may not be very annoying, depending on the sensitiveness and cleanliness of the patient. On the other hand, they may at times be severe enough to disturb sleep.

Examination reveals a characteristic picture of diffuse redness about the introitus, with foamy fluid pus which is often mistaken for gonorrhea. The vagina may be diffusely red or reddened in patches. Sometimes there is little to be seen in spite of moderate symptoms. The increased vascularity and succulence, which is the most striking change in the vagina of pregnancy, should not be mistaken for evidence of trichomonas, nor should a moderate secretion be overlooked as a normal condition. The normal secretion of pregnancy is represented by a thick, white, crumbly substance, which possesses a distinctly acid reaction and is composed of epithelial cells and debris, and a great many Doderlein bacilli.

The diagnosis is readily made by placing a little vaginal secretion in two or three drops of physiologic solution of sodium chloride on a slide covered with a cover slip and examined microscopically under the high dry lens, or the hanging drop method may be used. The parasites are easily seen by their motion and often aggregate clumps of cells or debris in which they become entangled. They vary in size but are usually a little larger than a pus cell. Stained smears are not used for diagnosis, because of the difficulty in differentiating the parasite from pus cells unless specially prepared.

The secretion for examination should be taken from the fornices and not from the cervix, as trichomonas is apparently not found in the alkaline cervical secretion. Specimens may be obtained by a platinum loop or from the lower blade of a bivalve speculum. Even simpler, when the examination is finished, the gloved finger is dipped into two or three drops of saline solution on a slide. The adherent secretion is generally sufficient for examination. If the latter method is used one should have no antiseptic solution, lubrication jelly or dusting powder on the gloved finger as the trichomonas is easily affected and if not killed may become amotile.

TREATMENT

The multiplicity of treatments indicates that a satisfactory method has not been obtained. All relieve the symptoms, but reinfection is very prone to occur. This

may be due to the fact that as yet the life cycle or focus of the parasite is not known. The methods used can be divided into two types: (1) those in which douches or tampons are used with various antiseptics, usually preceded by scrubbing of the vagina with tincture of green soap, and (2) the drying or powder treatment.

The treatments used in nonpregnant cases, which are rather drastic, are employed in modified form in cases of pregnancy. Hoehne washes the vagina with 1 per cent corrosive mercuric chloride followed by a glycerin mixture containing sodium bicarbonate or sodium borate. De Lee¹⁹ favors this method but advocates putting the patient to bed for two days during the treatment. Schmid and Kammer have used this method with fairly good results. Greenhill, after scrubbing the vulva and vagina with tincture of green soap, uses methylene blue (methylthionine chloride) tamponades followed by 0.5 per cent lactic acid douches. Mohler²⁰ injects a solution of Doderlein bacillus culture and lactose into the vagina with a syringe. Hibbert²¹ uses a specific streptococcus bouillon filtrate. Cornell and his associates have used mercurochrome, methylene blue, gentian violet, acriflavine hydrochloride, glycerin with and without sodium bicarbonate, tincture of iodine, hexylresorcinol, lead acetate, zinc oxide ointment, metaphen and the like and they advocate the Kleegman²² treatment, which consists of scrubbing the vagina with tincture of green soap, painting with pyrolytic acid and insertion of Lassar's paste²³ tampons. Holden uses kaolin as a drying powder. Bland precedes the kaolin with 1 per cent trinitrophenol and follows with douches of compound solution of iodine. Sure and Bercey²⁴ use quinine sulphate with insufflation. Northrup²⁵ advises powdered sulphur, and Gellhorn²⁶ has obtained good results with acetarsone (stovarol).

My associates and I have tried a number of these methods, which relieved many but were not entirely satisfactory. Lately we have used with very good effect a pure crystalline phenol in an acid medium, notably boric acid powder instead of the usual sodium bicarbonate, as the sodium bicarbonate often produces an irritation. Essential oils are added for their cooling effect. In acute cases the patient is allowed to take daily douches (from 1 to 2 drachms to a quart of water) for one or two weeks, which relieves the symptoms and allays the irritation. The vagina is then swabbed with a cotton pledget and the dry powder mixed with three times its volume of boric acid powder, is instilled into the vagina, the patient being instructed to take a douche with warm water the same evening or the next morning. As the phenol content of the douche powder averages from 6 to 8 per cent, it must be mixed with at least three times its volume of boric acid powder before it is used dry in the vagina. If used full strength in a sensitive patient, it may cause a severe burn, as did occur in one case.

In a number of patients who harbored the organisms during pregnancy and had no treatment, a spontaneous cure occurred during labor and the puerperium. Follow-up examinations found them to be free from infec-

tion Two of the latter patients became pregnant shortly thereafter and again showed the parasites

CONCLUSIONS

1 Vaginal discharge during pregnancy is often dismissed as a normal physiologic change but is frequently associated with *Trichomonas vaginalis*

2 In a series of 309 pregnant patients personally examined, *Trichomonas vaginalis* was found in 207 per cent

3 The symptoms are essentially the same as in the nonpregnant, and the diagnosis is easily made by a hanging drop

4 My cases showed no increased puerperal morbidity

5 The multiplicity of treatments indicates that a satisfactory method is not available, but we offer the use of a crystalline phenol powder which has been used with good effect in our series

6 Some cases are apparently cured spontaneously during labor and the puerperium

7 The life cycle of the trichomonas requires further study, but in the meantime many patients may be given much relief from the annoying symptoms and leukorrheal discharge associated with this organism by more careful attention to the microscopic examination of the vaginal secretion

THE LATENT PERIOD IN THE ROENTGEN DIAGNOSIS OF PULMONARY TUBERCULOSIS

PRELIMINARY REPORT

LEO G. RIGLER, M.D.

MINNEAPOLIS

AND

FREDERICK B. EXNER, M.D.

BELLINGHAM, WASH.

The roentgenologic diagnosis of pulmonary tuberculosis stands today on a firm foundation. It is generally conceded that tuberculous lesions in the lungs can be recognized at their earliest stages in the roentgenogram, often long before physical signs are present and frequently in advance of recognizable symptoms. The increased utilization of this method for the routine examination of the chest has resulted in a vast increase in the number of cases of incipient tuberculosis that have been recognized.

This development of our ideas as to the place that the roentgenogram should have in the recognition of pulmonary tuberculosis depends largely on the pioneer work of Cole, Dunham, Pancoast, Baetjer, Brown and Sampson, and Amberson. Williams and Hill's¹ study established firmly the superiority of the roentgen over the physical examination in the detection of minimal tuberculosis. Webb² summarized well the situation in this regard, and since then there have been numerous contributions which reflect the opinion that the roentgenogram is by far the most sensitive recorder of early pulmonary tuberculosis.

The statement has been repeatedly made³ that in the presence of symptoms due to pulmonary tuberculosis the roentgen examination should reveal evidences of the disease in practically all cases. It has been said also that pulmonary tuberculosis might be present in the lungs without roentgen signs if it was of such a nature that it produced no symptoms. This appears to be borne out by cases without symptoms or signs in which the roentgen examination, made as a routine procedure, proves negative while later events indicate that a pulmonary lesion was probably present at that time.

There is, however, little accurate or definite evidence bearing on the question of how long a period must elapse from the time of the infection itself until roentgen manifestations first appear. The opinion is widely held that tuberculous lesions remain concealed for long periods before developing sufficiently to produce symptoms or signs. While numerous observations have been made as to the rapidity of development of tuberculosis in the lungs of animals after the artificial introduction of tubercle bacilli, there is very little specific evidence on this point in human beings. Redeker⁴ has reported some cases of primary tuberculous infection in which the presumption that the infection occurred at a certain time is very strong because of the history of exposure, and evidences of tuberculosis in the roentgenogram appeared approximately four months later. The observation of roentgenographic changes in the chests of young children within relatively short periods after a known exposure to tuberculosis has been made. Ligner⁵ has reported a case in an infant in which the roentgen signs appeared within ten days after the tuberculin skin test became positive. There was a period of at least twenty-five days between the occurrence of the infection and the development of definite changes observable in the roentgenogram. Aside from these few observations, no statements can be found in the current literature or in standard textbooks as to the matter.

Wessler and Jaches⁶ state that there must be an area of infiltration near the surface of the lung at least 4 mm in diameter to be visible on a roentgenogram. They observe that a tuberculous focus can exist without roentgen evidence of its presence, and a latent period intervenes during which the focus gets larger and finally becomes evident. The time consumed by this latent period is not given. McPhedran⁷ believes that a tubercle from 1.5 to 2 mm in diameter can be seen in the roentgenogram but also does not state how long a period must elapse before this size is attained. Fishberg⁸ gives the clear impression that long periods may elapse between the occurrence of a tuberculous infection of the lungs and the appearance of roentgen signs. He believes that an active tuberculosis may be present without roentgenographic signs. He also states that it takes about eight weeks for a tubercle to develop.

It is obviously most difficult to date actually the occurrence of a tuberculous infection in the human being. It is often possible to state with accuracy the time of onset of symptoms, but that may be long after the onset of the infection. Only one means of great accuracy is at hand, i. e., the tuberculin skin test. That

this is a most accurate means of indicating the presence or absence of tuberculous infection has now been well established, as shown by the recent work of Hart⁹ and Myers¹⁰ and the opinion of Fishberg⁸ and others. The interval between the occurrence of the infection and the establishment of a positive skin test must be very short, probably only a few weeks or less.¹¹ A negative tuberculin skin test, except under unusual circumstances, is extremely good evidence of the absence of a tuberculous infection. By most observers, in fact, it is considered to indicate that the patient has never been infected with tuberculosis. In some instances, however, this may not be true, as the allergy may disappear, leaving a negative tuberculin skin test in an individual who had had a primary infection in childhood. In the young adult this is rather unlikely, but this possibility makes it difficult to state definitely that any particular individual has never had a tuberculous infection. A positive skin test has, of course, much less significance, indicating only that an infection has occurred at some time, and it has no imperative relationship to the present symptoms of any patient. When however, a negative tuberculin test is followed in a relatively short time by a positive one, and a definite exposure to tuberculosis has taken place in the meantime, it seems justifiable to date the occurrence of the infection to some time during the interval between the two tests. It is assumed, of course, that the tests are properly done and properly interpreted.

With the increased use of the tuberculin skin test as a routine procedure, especially among university students, nurses, interns, school children and others, cases of the type previously cited are being observed.¹² If, in such cases, roentgenograms of the lungs were made prior to the negative skin test, promptly after the positive skin test and at frequent intervals thereafter, some idea of the duration of time that must take place between the occurrence of a tuberculous infection of the lungs and the development of roentgen signs might be obtained.

It must be noted that this can apply, in the majority of cases, only to a first infection or childhood type of tuberculosis. It is generally agreed that the adult type of tuberculosis rarely, if ever, occurs in individuals who have not had a childhood infection. The vast majority of persons, therefore, who develop the adult form of tuberculosis must already have a positive skin test. In that event there is no sure means of dating the occurrence of the infection. On the other hand, first infections no doubt occur frequently in young adults, and these lend themselves particularly well to this type of study. In the typical first infection tuberculosis, as seen in young children, the development may be very rapid, and the lesions are detected in the roentgenogram with ease because of their extensive character. In the group of young adults with first infection whose cases are to be reported here, the lesions had more the roentgenographic characteristics of the adult type of tuberculosis, so that their detection was not much easier than that of any early adult type of lesion. While the development may have been more rapid than that of the usual adult type of tuberculosis, nevertheless a study of these cases will throw some light on the minimum time which must elapse before the roentgenogram will reveal a tuberculous infection of the lungs even if the maximum time is not clearly demonstrated.

We have been fortunate in observing a number of cases of pulmonary tuberculosis developing in medical students and interns who have previously had repeated tuberculin skin tests, chiefly by the Mantoux method, 0.1 mg of old tuberculin being used in most cases and also have had repeated roentgenograms of the chest. Some of these are included in the report of Myers.¹² For a number of years, under the direction of the Student's Health Service, all the medical students of the University of Minnesota have had routine tuberculin skin tests and roentgenograms of the chest at yearly intervals. We have therefore been able in some of these cases to trace exactly the time of onset of the infection and the period of time that elapsed before roentgen signs in the lungs became apparent. The important detailed incidents in these cases are tabulated farther on. It must be noted, however that we have

Fig 1 (case 1)—Diagrammatic representation of roentgenograms of chest showing only the upper portions: a normal chest showing vascular markings this was made almost six weeks after the first day of exposure to tuberculosis and about four weeks after the first positive tuberculin skin test; b first positive film taken about eighteen weeks after the first tuberculosis exposure note the characteristic nodular infiltration in both subclavicular regions; c film made about six weeks later note the increase in the area of infiltration and the establishment of a drainage band especially on the right.

not attempted to record all the cases studied, or even all the cases in which the skin test changed under observation. We have, rather, selected a group of cases with a fairly definite exposure to tuberculosis in which a positive skin test and definite roentgen signs developed.

CASE 1—Nov 21, 1928 Pirquet negative
Jan 16, 1930 Mantoux negative, 0.1 mg Roentgenogram of chest negative
Jan 3, 1931 Mantoux negative, 0.1 mg Roentgenogram of chest negative
Dec 19, 1931 Known exposure to tuberculosis, first day
Dec 23, 1931 Mantoux negative, 0.01 mg Roentgenogram of chest negative
Dec 31, 1931 (12th day) Mantoux positive, 0.1 mg
Jan 27, 1932 (39th day) Roentgenogram negative (fig 1 a)¹³

¹³ Owing to the difficulty of reproducing the fine changes shown in the roentgenograms all the illustrations are diagrammatic faithfully representing the original films.

Feb 20 1932 Mantoux positive, 0.1 mg Physical examination negative

March 17 1932 In bed with cold

April 23, 1932 (125th day) Roentgenogram positive (fig 1b) Physical examination negative Temperature normal

June 2, 1932 Roentgenographic observations increased (fig 1c) Slight afternoon fever

April 6, 1933 Roentgenographic observations decreased No symptoms or physical signs

In this case there was a definite exposure followed very shortly by a positive skin test. The roentgenogram made more than five weeks later was entirely negative (fig 1a). Sixteen weeks after the positive skin test and less than eighteen weeks after the first known exposure to tuberculosis the roentgenogram (fig 1b) was clearly positive. Unfortunately, no films were taken in the interim. Judging from the extent of the lesions shown in figure 1b it seems highly probable that roentgenographic evidence could have been detected

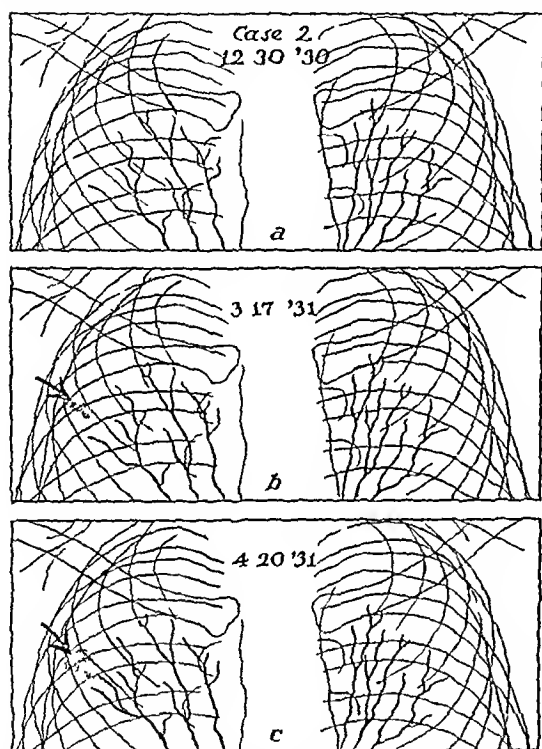

Fig. 2 (case 2)—Diagrammatic representation of roentgenograms of chest showing only the upper portions: a normal chest showing vascular markings; this was made a few days after first tuberculosis exposure; b first positive film taken about eleven weeks after the first exposure; note the small irregular nodule in the right upper lobe some distance below the clavicle; c film made about five weeks later; the nodule has increased so that the changes are much more definite.

a month or two earlier. There were no physical manifestations at any time. The roentgen manifestations have now persisted with some increases and some recessions for about twelve months.

The character of the roentgen observations is worthy of some note. There was a rather nodular type of infiltration in both infraclavicular regions (fig 1c). This was surrounded by a zone of haziness, although the nodules themselves were fairly well demarcated. Repeated roentgenograms at monthly intervals have shown both recessions and accretions in the size of the lesions until the last which shows some decrease. The appearance is very similar to that described as an early adult type of tuberculosis by Wessler and Jachess¹³ Assmann¹⁴ and others. The repeated negative tuber-

culin skin tests obtained before this exposure strongly suggest that this was a first infection. Nevertheless, the possibility that this was a second infection in an individual who had lost his allergy cannot be excluded.

CASE 2—Jan 1, 1929 Pirquet negative

Feb 27, 1930 Mantoux negative, 0.1 mg Roentgenogram negative

Dec 26, 1930 Known exposure to tuberculosis, first day

Dec 30, 1930 (4th day) Roentgenogram negative (fig 2a)

Jan 5, 1931 (10th day) Mantoux negative, 0.1 mg

March 8, 1931 Known exposure to tuberculosis

March 14, 1931 (78th day) Mantoux positive, 0.1 mg

Roentgenogram positive with minimal signs (fig 2b)

April 20, 1931 Mantoux positive, 0.01 mg Roentgenogram positive with increased signs (fig 2c)

June 5, 1931 Pleurisy with effusion, same side as lesion

April 17, 1933 Roentgen signs hardly discernible. Some thickening of pleura

In this case the exact sequence is less clear because of the two exposures to tuberculosis. In view of the presence of roentgen signs six days after the beginning of the second exposure (fig 2b), it seems most reasonable to assume that the first exposure produced the lesion in spite of the negative skin test following this exposure. The latter was done only ten days after the beginning of this period, so it might still have been negative, even though an infection had occurred.

Assuming that the infection occurred with the first exposure there was an interval of only eleven weeks from the first day of the contact until the roentgen signs were first observed. The later development of the pleurisy with effusion served merely to confirm the diagnosis.

A small rounded nodule was observed in this case in the periphery of the right upper lobe (fig 2c), which would correspond well with a primary tuberculous focus as often seen in childhood. It is notable that it did not increase in size but did persist for a long period. On the last examination, some two years after the original finding, the lesion could be identified only with difficulty.

CASE 3—Jan 20 1930 Roentgenogram negative

Feb 19, 1930 Mantoux negative, 0.1 mg

Jan 30 1931 Roentgenogram negative

Feb 25 1931 (1st day) Mantoux positive (+), 0.1 mg

March 3, 1931 (6th day) Mantoux positive (+++), 0.1 mg

May 5 1931 (69th day) Roentgenogram positive (minimal signs) Pleurisy with effusion occurred shortly

April 11, 1933 Roentgen signs hardly apparent

In this case there was no known exposure to tuberculosis. The change in the skin test was definite, however, and was followed in a relatively short time by the symptoms of an acute pleurisy. It is more difficult to date the occurrence of the infection, because a whole year intervened between the last negative and the first positive skin test. In view of the fact that the roentgenogram of Jan 30, 1931, was negative and that the first skin test of Feb 25, 1931, was only slightly positive while in a short time it became strongly positive it seems reasonable to assume that the infection occurred at about that time. We can say with certainty only that positive roentgen signs appeared within about ten weeks after the first positive skin test. Repeated roentgenograms since that time have demonstrated the persistence of the small nodule in the upper lobe, which was first observed. This nodule was very similar in appearance and location to that illustrated in case 2 (fig 2). The pleurisy with effusion merely tended to confirm the diagnosis. The final roentgenogram almost

two years later showed almost a complete disappearance of all the changes

CASE 4—Dec 12, 1929 Mantoux doubtful probably negative 0.1 mg
Jan 10, 1930 Roentgenogram negative
Jan 23, 1931 Roentgenogram negative (fig 3a)
Jan 23, 1931 Mantoux negative, 0.1 mg
Sept 15, 1931 Known exposure to tuberculosis first day
Sept 15, 1931 Mantoux negative, 0.1 mg Roentgenogram negative
Oct 15, 1931 (30th day) Mantoux positive (++) 0.1 mg
Jan 19, 1932 (126th day) Roentgenogram positive (very slight) (fig 3b)
May 30, 1932 Roentgenogram positive (marked) (fig 3c)
Dec 13, 1932 Roentgenogram shows some diminution of the condition

In this case an exposure to tuberculosis for a month was followed immediately by a change in the skin test from negative to positive. The first roentgenogram (fig 3b) was taken eighteen weeks after the first known exposure and about thirteen weeks after the first positive skin test. The original interpretation of this examination was negative, but reexamination of these films after the observation of the rather marked changes four and a half months later showed clearly the presence of a small nodule in the apex where the subsequent changes were seen.

The roentgen observations in case 4 are unusually interesting. The character of the infiltration in the right apex (fig 3c) was typical of what is ordinarily considered to be an adult type of tuberculosis. The occurrence of the lesion in connection with the skin tests, as recorded makes it appear that this was a primary infection and indicates how difficult it is to determine from the roentgenogram alone whether a lesion is of the primary or of the adult type. Again the possibility that this was a true adult type in an individual who had lost his sensitivity to tuberculin as previously stated, must be strongly considered.

CASE 5—Nov 16, 1928 Pirquet negative
Nov 10, 1930 Known exposure to tuberculosis first day
Nov 11, 1930 Roentgenogram negative
Jan 12, 1931 (63d day) Mantoux negative 0.1 mg
April 10, 1931 (151st day) Cervical nodes enlarged (biopsy later showed tuberculosis)
April 11, 1931 (152d day) Mantoux positive 0.01 mg
May 1, 1931 (171st day) Roentgenogram positive
June 6, 1931 Roentgenogram shows more marked lesion (incipient bilateral apical)

In this case the enlarged lymph nodes presented the first physical evidences of tuberculosis. There was an interval of twelve weeks between the last negative and the first positive skin test. The roentgenographic observations appeared almost simultaneously with the positive skin test, and the negative roentgenogram five months earlier indicates the recent character of these observations. The increase in the lung changes also indicates the active character of the lesion. The exact date of the infection is difficult to determine but was most probably dated at the time of the known tuberculosis exposure in spite of the negative skin test nine weeks later. If this date is assumed the positive roentgen signs appeared within twenty-four weeks after the earliest possible occurrence of the infection. In this case also the roentgen manifestations were those of an adult lesion there being a bilateral apical involvement of a rather fibrotic type, very similar to that in case 4.

From the records of these five cases it appears that an interval of from eleven to twenty-four weeks may

elapse from the occurrence of a tuberculous infection to the development of roentgen signs that are susceptible of interpretation as indicating pulmonary tuberculosis. This obviously represents only the minimal time. It is possible that in some cases the minimal time may be even less. This might have been demonstrated if roentgenograms had been made at weekly intervals after the occurrence of the positive skin test. What the maximum time would be it is impossible to state. It is striking that the roentgenographic manifestations should appear so quickly and it is notable that in none of these cases were there any physical changes determined or absent. In the others the symptoms were conditioned by the acute pleurisy or the presence of tuberculous lymph nodes.

The data here presented tend to confirm abundantly the assertion that the roentgenogram is a most sensitive

Fig 3 (case 4)—Diagrammatic representation of roentgenograms of chest showing only the upper portions. *a* normal chest shown in film taken about nine months before the first tuberculosis exposure. *b* first positive film taken eighteen weeks after the first tuberculosis exposure. *c* note the very small nodule in the right apex. *c* film made more than four months later the changes have greatly increased the whole appearance suggesting a fibrotic apical adult lesion.

method of detecting pulmonary tuberculosis in its earliest stages. It gives also some practical information bearing on the question of when it would be wise to make a roentgen examination of an individual after a tuberculous contact to determine whether an infection has occurred. It is evident that rarely will any information be obtained in this way until after the skin test becomes positive. Following this, a latent period of from three to six months possibly less, must elapse before any roentgen changes will appear. How much longer the case must be followed, beyond the six months period, before a pulmonary lesion can be ruled out it is impossible to say. Our experience thus far suggests that the lesions will be demonstrable by this time, but this is not clearly proved. As the length of time becomes prolonged, observations such as those

reported here become much less valuable, because of the possibility of a new exposure occurring and thus producing changes that might be assigned to the original exposure. For this reason any statement as to the maximum latent period would be most inaccurate if based on an observation of the ordinary human case.

It should be noted that these observations are based on a relatively small number of cases. It is obviously difficult to collect a large number of cases in which the coincidence of events detailed here occurs, and in which such close observations have been made. Nevertheless, the observations in these five cases have been so consistent and are in such accord with the previously known data that the conclusions derived are highly credible. It is hoped that this paper will direct the attention of those who are doing routine tuberculin skin tests and roentgen examinations of the chest to the possibility of making such observations, so that a larger body of cases may be collected.

SUMMARY

Careful observations in five cases of tuberculous infection in young adults seem to indicate the following:

1 The roentgenogram is an exceedingly sensitive method of detecting pulmonary tuberculosis.

2 A minimum latent period of from three to six months may elapse between the occurrence of a tuberculous infection and the appearance of roentgenographic changes.

3 The maximum period of delay in the development of roentgen changes cannot be determined.

MULTIPLE SCLEROSIS

CERVICODORSAL SYMPATHECTOMY AS A RELIABLE MEASURE: REPORT OF A CASE

FREDERICK S. WETHERELL, M.D.
SYRACUSE, N. Y.

The therapeutics of multiple sclerosis has been a baffling problem since the time of recognition of the disease as a clinical entity, and the multiplicity of agents employed in attempts at relief of the condition signify their lack of specificity. Perhaps the best results, and those rather evanescent in their effects, have been obtained when some form of fever therapy has been employed. This includes the vasodilatation obtained by diathermy, hot baths and the like.

A surgical procedure, namely, cervicodorsal sympathectomy, following which a most remarkable alleviation of symptoms has occurred in five cases, is the matter under discussion in this paper. Four cases have been reported by Royle,¹ and one case is herewith reported.

A full discussion of the symptomatology of multiple sclerosis, with its protean manifestations, a detailed analysis of the newer conceptions of the pathology or of the minutiae of the rationale of the treatment here suggested would be monographic. Only a short discussion of these phases will be presented, the main object at present being to call to the attention of the profession of this country a method already tried,

which now appears to be the nearest approach to a solution of the problem of therapeutics yet presented.

SYMPTOMATOLOGY

It is now well known that the old triad of Charcot—nystagmus, scanning speech and intention tremor—manifests itself late in the disease. Many of the earlier symptoms are often overlooked and, because of the sudden remissions so characteristic in its beginning, are put down as hysterical attacks or mild apoplexies, or "rheumatism." Among these early manifestations are ocular palsies, transitory diplopias, muscular weaknesses, which are associated with giddiness, nausea and headache, stumbling and tripping, stiffness of the legs, and difficulty in climbing stairs, urinary frequency of sudden onset and cessation equally sudden,² slight difficulties in speech, and the like. Very often these disturbances follow or occur during a period of distress. Pregnancy, in a patient who has had previous attacks, causes an exacerbation almost without fail. In view of what follows, the analogy to hyperthyroidism and pregnancy is here emphasized, with its associated relation to the sympathetic nervous system.

PATHOLOGIC CHANGES

Charcot's description of the pathologic changes, consisting of a patchy loss of myelin, with relatively intact axis cylinders, perivascular infiltration, and dense glial infiltration, has not been markedly altered by later investigators. Plaques of sclerosis may be found in any part of the central nervous system.

Putnam⁴ has recently made an important contribution in which he shows that vascular abnormalities with concurrent disturbances of circulation, notably decreased vascularization around the plaques, may be an etiologic factor. He cites Pfeiffer,⁵ who found that a zone of capillary deficiency surrounded many of the smaller vessels of the brain. This allows the inference that many areas of brain tissue are chiefly nourished by transudation through a single vessel. It would follow, then, that a constriction of this vessel would cause a relative anemia of the surrounding area, the absence of actual tissue necrosis being due to a supply from a neighboring vessel. The plaques of sclerosis have a constant perivascular distribution, and, as has been shown, the reaction to the relative anemia is such that the more resistant axis cylinders and glial fibers do not degenerate as does the myelin.

These observations are important when considered in the light of animal experimentation, which shows that the circulation to the brain may be noticeably increased by section of sympathetic vasomotor fibers. Further investigations may show that sudden elimination of an irritating factor that is affecting the sympathetic supply, with the resultant increase in circulation due to vasodilatation,⁶ is a reasonable explanation for the remissions in the disease. Likewise, the fact that certain sympathetic nerve fibers may suddenly be free from irritation could account for the cessation of one manifestation of the disease while other symptoms remained stationary. This sequence of events might

be compared to the uneven distribution of the vasoconstrictor manifestations found in a vasospastic disease, such as Raynaud's, in which the fingers may be affected, or the toes, or both. The previous condition of the vessels in one digit may be a factor in the determination of whether that member rather than another is to be the seat of a terminal ulcer. The same argument might be advanced in relation to the circulation in various parts of the cerebrospinal system.

EXPERIMENTAL EVIDENCE

Decreased vascularization has been shown⁷ to result in myelin degeneration of the type found in multiple sclerosis and can be explained on the basis of an asphyxia or anoxemia of the tissue in the neighborhood of the involved vessels.

In a summary of his investigations Putnam says

The histological characteristics of the disease may be closely imitated experimentally by a number of different procedures, all of which have in common an interference with the blood supply of the affected area. These facts give a new importance to the vascular abnormalities which have long been recognized as a characteristic of sclerotic plaques. The ultimate etiological factor should probably be sought in a local vascular abnormality, or in some alteration in coagulability of the blood.

Royle⁸ has shown by animal experimentation on brains of living goats that there is an improvement in cerebral circulation following sympathetic trunk section. His observations relative to relief of venous congestion are interesting when considered in the light of Pfeiffer's studies, which show that the "perivascular free space" obtains part of its nourishment from the vein contained within it, and of Putnam's, that blocking of this venous supply produces acute lesions having a gross and microscopic resemblance to the lesion found in multiple sclerosis in man.

REPORT OF CASE

History—R E, a man, aged 57, referred to me by Dr R J McMahon of Endicott, N Y, was admitted to the Syracuse Memorial Hospital, Nov 6, 1933, with a diagnosis of multiple sclerosis. The examination was checked by Dr Noble Chambers, neurologist to the Memorial Hospital, who concurred in the diagnosis. The patient was unable to walk without the assistance of two strong men. He had a marked ataxia of both upper and lower extremities. Diplopia, nystagmus and scanning speech were present. Feeding himself was a practical impossibility because of intention tremor. It was impossible for him to write legibly. He was unable to arise from a chair and could not maintain his balance, even with the eyes open, when he was brought to a standing position. There was a marked euphoria present also forced laughter at times, which however, was not of the same degree as noted in pseudobulbar palsies. It was impossible to understand what he said, his wife, having become accustomed to the change in his speech, had to interpret for us.

All the foregoing had been present for eight years, with a gradual increase in severity. He had been practically bedridden for several years. He was troubled with constipation, requiring cathartics.

His past history and significant parts of his family history reveal that at 18 years and again at 39 he had attacks of disability which were diagnosed as "rheumatism." The latter attack disabled him for seven months. He states that he had pain in the joints and in his wrists at that time but that there was never any swelling. His brother a physician reports that there have been several cases of multiple sclerosis in relatives. He had never been operated on and except for a recent illness

during which there was jaundice due to cholelithiasis, as diagnosed at the Charles S Wilson Memorial Hospital at Johnson City, N Y, Sept 10, 1933, he had been well, except at 18 and 39, as stated.

Examination—The patient was very obese. In addition to the manifestations already enumerated, he had a blood pressure ranging between 175 systolic, 80 diastolic and 155 systolic, 90 diastolic, the former in September, the latter before operation November 8. The pulse was 82. Dr J G F Hiss, cardiologist, reported that a soft systolic murmur was present over the apex and as far as the anterior axillary line. A pulmonary systolic murmur, found by another examiner a few months previously, was not heard. There was no electrocardiographic evidence of disease (Drs Chambers and Hiss both felt that the attacks called rheumatism may have been early manifestations of multiple sclerosis). Tendon reflexes were normal, the abdominal reflexes were absent. The Wassermann reaction was negative. A diagnosis of multiple sclerosis, largely cerebellar in type, was made and several internists felt that the diagnosis was correct.

An examination of the eyes by Dr S B Marlow, attending ophthalmologist to Syracuse Memorial Hospital, showed that bitemporal pallor was lacking. There was a fine right lateral nystagmus present, and relative scotomas were present for red.

Operation—November 15, a right cervicodorsal sympathectomy was performed. The superior thoracic and the inferior cervical ganglions with the sympathetic trunk and connecting rami were removed. The posterior approach, as described by Henry,⁹ was used, with the exception that the first rib rather than the second was sectioned.

Following the operation a right-sided Horner's syndrome was noted. The blood pressure was right arm, 182 systolic, 120 diastolic, left arm, 188 systolic, 124 diastolic. Five hours after operation both his wife and a patient in the next bed were astounded at the improvement in his speech. This was very noticeable and commented on by every one in attendance on him, nurses and interns. While the possibility that this may have been a postanesthetic result was considered, the continued improvement beyond a period when this could have been possible argues against such a conclusion.

On the following day his nurse reported that he would not wear his glasses, saying that he could see better without them. Three days later a marked improvement of his intention tremor was noted. He said that his legs felt different and that he felt as if he could walk if he should be allowed out of bed.

All these manifestations of sudden improvement coincide with those in the cases reported by Royle.

The speech improved daily, enunciation becoming clearer, and slurring was markedly lessened when he did not attempt to hurry his speech. He was delighted to be able to pronounce the words "cookie" and "calculate" distinctly—words that were among the first with which he had difficulty in the beginning of his illness.

December 6 the left side was operated on the same procedure being followed as on the right. A bilateral Horner's syndrome was present following this operation. He was discharged from the hospital, December 22.

The improvements noted at that time were briefly as follows:

Possibly the disks had a better color, but this was uncertain.

He said that his eyesight was much better.

Constipation was no longer present.

He was able to hold a glass of water with one hand and could feed himself.

He could pick up a safety pin without evidence of intention tremor.

He wrote much better unless he was tired following exercise.

He was able to get up from a rocking chair and stand with his eyes closed.

He could walk several hundred feet, leaning on his wife's arm.

These observations were checked by numerous persons interested in the case.

Jan 7, 1934, Dr McMahon and I, after examining the patient at his home and after conversing with his wife,

9 Henry A H Exposures of Long Bones New York William Wood & Co 1927

⁷ Ferraro Armando Experimental Toxic Encephalomyelopathy Diffuse Sclerosis Following Subcutaneous Injection of Potassium Cyanide Arch Neurol & Psychiat 29 1364 (June) 1933

⁸ Royle N D Alteration of the Circulation of the Brain by Surgical Means in Diseases of the Central Nervous System Brit M J 1 1063 (June 11) 1932

recorded that in general there was an improvement of 40 per cent. In some respects even a greater improvement could be recorded. This was particularly true with regard to enunciation. He pronounced such words as "liquid electricity" and "truly rural" very distinctly. The patient noticed a daily increase in general strength. Asked to stand from a sitting position on a low davenport, he arose easily and without the assistance of his arms. He stood with his eyes closed and feet together, maintaining his balance perfectly. He was able to read and remembered the thread of the article or story. The finger to nose and finger to finger tests were approximately 90 per cent perfect. The same applied to the heel to knee test. He did not require cathartics. His wife had noticed that he fed himself better than he did, that there was a decided improvement in his temperament, and that he was definitely stronger in every way.

These observations regarding improvement coincide closely with those in the cases reported by Royle. For this reason justification may be granted for reporting them so soon after operation.

Dr McMahon reexamined the patient with a view to recording percentage improvements and wrote as follows, January 12:

My impression of the result of this operation on Mr. E. is that he has, to date, been benefited somewhere between 30 and 50 per cent. His speech, I believe, is at least 75 per cent better. The ataxia of his upper extremities somewhere between 30 and 50 per cent. He is able to get out of a chair unassisted and to stand with his eyes closed—something that he never could do since I have known him. He certainly can pick up a glass of fluid and feed himself much better than when I sent him to you. He is able to walk across the room unassisted but still lacks confidence. His wife tells me that when they are alone he goes all over the house but when he thinks he is being watched he is like a child learning to walk. He gets excited and needs a little reassurance simply taking a hold of some one's hand being enough to steady him.

SUMMARY

1. In a case of multiple sclerosis marked improvement was noted following a bilateral cervicodorsal sympathectomy.

2. The experiments quoted tend to rationalize the procedure on the basis of improved circulation and decreased irritation in the central nervous system.

3. Four cases reported by Royle show improvement similar to that noted in the case here reported. His oldest case shows improvement over a period of eighteen months.

4. The possibility that a sudden remission took place in five cases following the procedure outlined is extremely remote.

514 Medical Arts Building

The Student of Internal Medicine—Poll the successful consulting physicians of this country today and you will find they have been evolved either from general practice or from laboratory and clinical work. Many of the most prominent having risen from the ranks of general practitioners. I once heard an eminent consultant rise in wrath because some one had made a remark reflecting upon this class. He declared that no single part of his professional experience had been of such value. But I wish to speak here of the training of men who start with the object of becoming pure physicians. From the vantage ground of more than forty years of hard work, Sir Andrew Clark told me that he had striven ten years for bread, ten years for bread and butter, and twenty years for cakes and ale, and this is really a very good partition of the life of the student of internal medicine of some at least since all do not reach the last stage—Sir William Osler. Internal Medicine as a Vocation. Address delivered before the New York Academy of Medicine 1897.

Clinical Notes, Suggestions and New Instruments

LIGATURES AND SUTURES OF ALLOY STEEL WIRE*

W. WAYNE BARCOCK, M.D., PHILADELPHIA

From its resistance to chemical change, modern alloy steel has been called the new noble metal. Soft or annealed stainless steel wire has marked tensile strength, stretches over one third of its length before breaking, and has such resistance to corrosion that when buried in the tissues for prolonged periods of time it remains untarnished and does not give rise to tissue discoloration or local irritation. After three months under a plaster cast skin sutures of the wire retain their brilliant luster and show no tendency to irritate the tissues. For surgical purposes it may be substituted for the weaker and more brittle silver and bronze wires and replace, with advantage, horsehair, silk, and "dermal" as a fine approximating suture, and silkworm gut as a strong supporting through and through suture. The finer wire may readily be tied in the ordinary square knot without breaking or losing appreciable tensile strength and may even be used to ligate blood vessels. Encouraged by the toleration of living tissue for the wire, I have occasionally buried interrupted sutures and ligatures of fine wire in both septic and clean wounds to avoid the tissue reactions to catgut and silk. While further experience is desirable it would seem that these insoluble bits of metal should cause no more trouble than the larger silver clips used in intracranial surgery. For delicate approximating sutures and for ligatures I would advise the 36 or 35 B & S gage (0.0007 inch), which is the size of a fine hair and has a tensile strength of about 2½ pounds. For supporting sutures, the 30 B & S gage with a tensile strength of about 15 pounds is strong enough to support an ordinary abdominal wall. When applied as a ligature, a hemostatic forceps should be used in tying, to make sufficient traction to seat the knot firmly. The larger sizes, as used for the retention of broken bones, should also be tied by the traction of hemostats. The ends should be cut close to the knot, an old pair of scissors being used. In introducing a running suture, care should be taken not to kink the wire. The operating nurse should also be instructed to roll the wire carefully from one spool to another to avoid the kinking and twisting produced in careless winding. To its ease of handling, impermeability and other good qualities may be added that of cost. Nearly a mile of the fine stainless steel wire may be purchased for one dollar.

CONGENITAL STENOSIS OF THE LARYNX

RICHARD W. WILKINSON, M.D., WASHINGTON, D. C.

Congenital stenosis of the larynx is a comparatively rare condition. Not more than twelve cases have been recorded in the literature within the past decade. Textbooks on laryngology give little more than mention to the subject. Within all probability numerous cases occur but are not diagnosed owing to death at birth or shortly after by asphyxia.

True congenital stenosis is limited to atresia, bands or webs occurring within the glottis, involving the vocal cords, ventricular bands or arytenoids, and is permanent unless relieved by some surgical method. This condition should not be confused with the commonly seen congenital laryngeal stridor that results from an abnormal flaccidity of the epiglottis which is usually elongated, or abnormal flaccidity or thickening of the aryteno-epiglottic folds. The majority of such cases need little treatment, and the condition is outgrown.

Jackson¹ states that the most frequent lesion of congenital stenosis of the larynx is a web or band situated at the anterior

¹ Jackson, Chevalier and Coates, G. M., The Nose, Throat and Ear and Their Diseases, Philadelphia, W. B. Saunders Company, 1917, p. 753.

commisures and they may extend to or beyond the middle of the glottis. The atresic type is very rare and usually incompatible with life. The case that I report in this paper is of the atresic type.

Many theories have been advanced as to the etiology of this condition. Congenital syphilis has been blamed, but little support is offered this theory. Clerf² recently reported three cases, two of which were in brothers, but he feels that there are too few cases to justify placing etiology on heredity.

According to Clerf the embryologic fusion theory is most tenable and is generally accepted. Embryologically there is a period of fusion of the structures of the glottis, apparently a provision on the part of nature to prevent passage of the amniotic fluid down the respiratory tract. Later, about the eleventh week, there is a period of dissolution, at which time the arytenoid folds or swellings separate followed by the superior and inferior folds parting to form the ventricular bands and the vocal cords proper, thus gradually forming the open glottis, which is seen at birth.

When stenosis occurs it is the result of incomplete separation of the fusion process and there remains a base of mesoderm covered with epithelium forming an atresia or in an attempt to separate, forming a band or web, which may be of variable thickness.

The symptoms depend on the impairment of laryngeal function. Small bands at the anterior commissure may cause little or no disturbance of respiration or phonation. Greater degrees of closure result in respiratory and vocal difficulties of a serious nature. In some cases laryngeal stridor may be the only symptom. This is usually heard both on inspiration and on expiration whereas congenital laryngeal stridor is heard only on inspiration.

The diagnosis is made by direct laryngoscopy in the young and by direct or indirect methods in older subjects. Dean³ states that this condition is not so rare and many cases would be recognized if the Washington University procedure were followed of examining every infant with an abnormal cry or stridor of any type.

The treatment depends entirely on the severity of the stenosis. In cases in which there is no dyspnea little need be done. Jackson's⁴ method is to incise the web along one cord only and allow it to flap down thus preventing adhesions during the healing process. Bands are excised or removed with punch forceps. When the cords themselves are adherent, they are separated by median incision. Surgical diathermy has been recommended by Arbuckle⁵ and others. Repeated bouginage is usually employed following any of these operative procedures, as adhesions are very prone to form. In infants and young children, tracheotomy is at times necessary to facilitate the operation and subsequent bouginage.

REPORT OF CASE

S. R., a girl, aged 7, seen, July 7, 1933, had frequent attacks of dyspnea, easily elicited by excitement or a slight infection of the upper respiratory tract. She spoke with a whisper that could not be heard farther than the distance of 1 foot.

The past history, related by the mother, revealed that the labor was normal and that immediately after delivery she noticed that the child did not cry naturally but with difficulty, emitting a feeble, high pitched sound. During infancy there were frequent attacks of severe dyspnea to the point of cyanosis. These attacks diminished in frequency with growth but were easily produced by any excitement or mild coryza. There was no history of childhood diseases other than measles, the personal history and the family history were negative for syphilis and tuberculosis. The child was well nourished and of healthy appearance. General physical examination was negative except for a small umbilical hernia and enlarged tonsils. The Wassermann reaction negative.

Examination by direct laryngoscopy revealed an atresia of the free borders of the vocal cords anteriorly, reducing the glottis to half its normal size. The remainder of the larynx appeared normal, with good movements of the arytenoids and

posterior halves of the cords. At this time attempts to dilate the stenosis were made with Jackson's brass bougies, without success, owing to the thickness of the atresia. Several days later, under general anesthesia, the cords were separated to the anterior commissure by a median incision with practically no hemorrhage. Reacting from the anesthetic, the child cried aloud for the first time in her life.

Under local anesthesia a week later direct examination showed the anterior borders of the cord adherent. This was easily broken down with dilators. At a subsequent examination it was necessary to incise adhesions at the anterior commissure, followed by bouginage.

The child has now a very slight atresia at the anterior commissure, the incised edges of the cords are a little roughened, the glottis is four-fifths patent, and movements of the arytenoids and true cords are normal. She has a normally audible speaking voice, which is slightly husky, and she has had no attacks of dyspnea since the first operative procedure.

COMMENT

Congenital stenosis of the larynx is a rare and interesting condition. Every infant with a persistent stridor or abnormal cry should have a laryngeal examination.

A CASE OF GAS GANGRENE TREATED BY INFILTRATION OF THE TISSUES WITH PERMANGANATE SOLUTION

FREDERICK C. WARNSHUIS, M.D. AND BERT VANDER KOLK, M.D.
GRAND RAPIDS, MICH.

B. B., a white man, aged 58, was brought to Butterworth Hospital, Dec. 16, 1933, at 1 p.m. from a railroad right of way, where he had been struck by a train. The right leg was frightfully mangled and, except for a band of skin, was severed at its midpoint. Measures to combat shock were immediately instituted and an amputation about four inches below the knee accomplished as soon as possible.

The postoperative course was not remarkable until the third day, when the patient became irrational with a temperature of 104°. At 3 p.m. of this day definite crepitation was elicited along the medial aspect of the amputation stump. The patient was isolated and all sutures were removed from the stump leaving the wound wide open. A continuous drip of permanganate solution 1:1000 was started into the wound. The crepitant area of the leg was infiltrated with a 1:500 solution of permanganate by means of a long needle and a Luer syringe. Then the mid thigh was infiltrated with the same solution, producing an encircling block. The patient was given 10,000 units of perfringens antitoxin intravenously. He became rapidly worse and at 8 p.m. was delirious and violent, so much so that an ether anesthetic had to be given to apply a restraining sheet. At 11 p.m. he seemed at least to be holding his own so amputation higher up was postponed. At this time the leg was again infiltrated and the fascial compartments were incised.

On the following day the laboratory reported a stormy growth of *B. welchii*. The patient was rational and seemed somewhat better. Ten thousand units of perfringens antitoxin was again given intravenously. The infiltration of the tissues with permanganate solution 1:500 was also repeated. In the afternoon of this day an extensive debridement of the sloughing stump was done. On the following day the patient's condition was definitely improved. No advancement of the gangrene was apparent, in fact, little crepitus could be detected. The infection did not extend beyond the infiltrated area. The patient was rational and quiet.

From that time on the patient's course was uneventful except for the removal of a small amount of slough Jan. 2, 1934. A severe secondary anemia was treated by repeated blood transfusions and the giving of iron by mouth. The patient improved steadily and on February 3 went home. At that time the stump was covered with healthy granulation tissue.

In a search of the literature we have been unable to find a report of any cases treated by infiltration of the tissues with permanganate solution. There are numerous references to the

DIPHTHERIA MORTALITY IN LARGE CITIES OF THE UNITED STATES IN 1933

ELEVENTH ANNUAL REPORT

This report concerns the ninety-three cities dealt with in the recent article on typhoid,¹ and the rates are calculated on the basis of the population figures used in that article. The number of diphtheria deaths in each city has been reported to us by the respective health department.² Particulars as to the years that are included in the five year averages annotated as "incomplete data" are given in footnotes to tables 1-8.

sible for Buffalo, Camden and Paterson to bring their diphtheria mortality to a lower point than that reported in recent years?

The cities in the South Atlantic states (table 3) have an average rate (3.49) more than double that of the cities of the Middle Atlantic division (1.47). Baltimore makes an excellent record, but the cities of sunny Florida (Miami, Tampa and Jacksonville) had in 1933 a considerably higher diphtheria mortality than most of the cities in the relatively inclement climate of New York and New England. Atlanta had one of the

Incomplete data.

highest diphtheria rates in the country (12.0), equaled only by Lowell, Mass. (12.0), and Dallas, Texas (12.0), but a large proportion of the deaths in that city was said to be among nonresidents.

The East North Central cities (table 4) make a fine showing. Chicago's record is indeed spectacular (02). Detroit also makes a new low record. This group of

cities had in 1925-1929 the highest average rate in any geographic division (11.21), it now has the next to the lowest (1.75). Here also sanitarians will watch with interest to see whether the change has a permanent basis or whether it is connected with one of the natural, if little understood, fluctuations sometimes manifested by this disease.

TABLE 7—Death Rates of Eight Cities in West South Central States from Diphtheria (Including Croup) per Hundred Thousand of Population

TABLE 9—Ten Cities with Highest Diphtheria Rates for 1933

Atlanta	12.0	El Paso	9.3
Dallas	12.0	Paterson	8.6
Lowell	12.0	Houston	8.3
Louisville	11.0	Chattanooga	8.0
Fort Worth	9.4	Knoxville	8.0

TABLE 10—Eleven Cities with No Diphtheria Deaths in 1933

Duluth	Salt Lake City	Springfield
Elizabeth	Seattle	Syracuse
Hartford	South Bend	Yonkers
Rochester	Spokane	

The cities of the East South Central division, with the exception of Birmingham and Memphis, do not show much improvement. Louisville seems to have had an excessively high diphtheria mortality, to judge from its own past record (table 5). Is it not about time for an intensive antidiphtheria campaign in some of these Southern cities?

The average for the West North Central cities (table 6) shows substantial improvement over that for the past three years. Duluth again leads the list and Omaha shows marked improvement over the three preceding years. Wichita and Des Moines, especially the former, seem to have recovered from their flurry of 1932.

The West South Central cities (table 7) bettered their average somewhat over 1932 but are still worse

off, on the whole, than they were in 1930 and 1931 New Orleans shows real improvement But why should there continue to be so high a diphtheria rate in Fort Worth and Dallas? The latter city, together with Atlanta and Lowell, had for the year 1932-1933 the highest diphtheria mortality in the United States in proportion to its population Thus cannot be pleasant

TABLE 11—Number of Cities with Various Diphtheria Death Rates

	No of Cities	40 and Over	30 and Over	10 and Over	5 and Over	Under 5	0 0
1890-1894	64	52	60	61	62	2	0

1932	37 054 712	1 191	3.21
1933	37 954 712	661	2.32†

* The five following cities are omitted from this summary because data for the full period are not available: Jacksonville Miami, Oklahoma City, South Bend and Ulen.

† Data for Fort Worth lacking.

‡ The rate for the ninety-three cities in 1933 is 2.33 (population 37 733 512, diphtheria deaths 881). The corresponding rate was 5.12 in 1930 3.72 in 1931 and 3.25 in 1932.

TABLE 13—Total Diphtheria Death Rates per Hundred Thousand of Population for Ninety-Three Cities According to Geographic Divisions

	(1932) Population	Diphtheria Deaths		Diphtheria Death Rates				
		1933	1932	1933	1932	1931	1930	1929
New England	2 931 505	70	91	2.66	3.65	4.85	4.57	8.34
Middle Atlantic	13 038 300	192	336	1.47	2.53	2.78	4.10	9.97
South Atlantic	2 375 007	83	76	3.49	3.29	4.42	3.65	7.37*
East North Central	9 719 600	171	249	1.75	2.65	4.23	7.79	11.21†
East South Central	1 242 500	85	76	6.84	6.11	6.87	5.00	6.34
West North Central	2 720 700	68	91	2.40	3.34	3.72	3.74	7.82
West South Central	1 991 700	132	160	6.73	8.16	5.93	6.43	9.24‡
Mountain and Pacific	4 025 700	80	138	1.99	3.43	2.71	3.59	6.28

* Lacks data for 1925 for Jacksonville and Miami.

† Lacks data for South Bend.

‡ Lacks data for Oklahoma City for 1925 and 1926.

reading for the Dallas chamber of commerce, and it is encouraging to learn that measures to remedy this condition are being undertaken.

The Mountain and Pacific cities (table 8) make a new low average. This group which ranked best in 1925-1929 is now quite outclassed for the second year in succession by the Middle Atlantic and East North Central cities. San Francisco continues to have a lower

rate than the climatic resorts San Diego and Los Angeles.

Many sanitarians will consider that the evidence in the tables here presented warrants a continuance of the efforts to lessen diphtheria mortality by immunization of susceptible children.

Council on Physical Therapy

THE COUNCIL ON PHYSICAL THERAPY OF THE AMERICAN MEDICAL ASSOCIATION HAS AUTHORIZED PUBLICATION OF THE FOLLOWING REPORT:
H. A. CARTER, Secretary

COLSON SAFETY INHALATOR ACCEPTABLE

The Colson Company, Elvira, Ohio, manufactures and offers for sale to the profession an electrically operated vaporizer Model NH-10. The unit may be described as a container having a heating coil on the inside and a connecting flexible tube, which conducts the vapor to the patient. It is recommended as an adjunct in the treatment of such diseases as pneumonia, laryngitis, croup, whooping cough, bronchitis and asthma.

The 400 watt immersion type heating element is located in the bottom of the kettle or water reservoir. A water tight seal is provided between the element and the kettle. The two concentric copper sleeves or cylinders that form the central vaporizing chamber are directly over the element. The space between these cylinders is sealed at the bottom to form a dead air insulating space between the water reservoir and the heating chamber. This keeps the water at a low temperature in the reservoir yet permits the water in the heating chamber to reach

a maximum temperature of 212 F and steam to be produced in less than four minutes after the current is turned on with the reservoir filled to the proper level with cold water. With warm water the time required is even less.

Colson Safety Inhalator

The medicine cup container is located at the top of the inner cylinder, the 'hot spot' of the Inhalator so that the medicine volatilizes quickly and the result is that the vapor administered contains a greater amount of medicine, insuring more satisfactory results. A curved tube conducts the steam from the inner chamber into the bottom of the flexible tube. The steam passing up the tube draws a current of cool air in through the intake opening and over the medicine cup. On the way up through the tube the volatilized medicine, cool air and steam are mixed, resulting in a medicated vapor of uniform quantity and temperature.

The Inhalator is prevented from overheating by means of an automatic thermostat, which is an integral part of the heating element. This prevents damage being done if the kettle should accidentally boil dry although care should be taken to see that the Inhalator is not allowed to remain without water for any length of time while the current is on.

The cover of the Inhalator is of cast aluminum and is held in place by means of four tie rods. It can be easily removed by unscrewing the four acorn nuts. The medicine cup can be removed from its holder through the filler opening. The proper water level mark to which the reservoir should be filled is visible on the inner cylinder through the water filler opening.

The chromium plated tube is 36 inches long and 1½ inches in diameter. It can be detached from the Inhalator top by unscrewing the large nut at its base. The bakelite tip is permanently fastened to the tube. The Inhalator base and top have a baked on crinkle finish and all exposed metal parts are bright aluminum or chromium plated.

The capacity of the Inhalator is approximately 5 quarts, which is said to be sufficient to operate it continuously for twelve hours. The overall diameter is 10 inches and the overall height to the top of the cover is $12\frac{1}{2}$ inches. The weight empty is $10\frac{1}{2}$ pounds and the shipping weight packed in corrugated shipping container is 14 pounds.

One unit has been investigated in a clinic acceptable to the Council. The construction appeared satisfactory and the claims made in the advertising matter and descriptive literature conformed with the Official Rules of the Council. The Colson Safety Inhalator, therefore, is included in the Council's list of accepted devices.

T J LEAK-PROOF ATOMIZER ACCEPTABLE

The T J Manufacturing Company, Attleboro Mass., submitted a product known as the T J Leak Proof Atomizer. This unit comes in a small box measuring about $1\frac{3}{4}$ by $\frac{1}{4}$

Leak Proof Atomizer

inches. It is so arranged that oil or other spray solution may be poured conveniently into the bottle. The nozzle is provided with a cap, which screws tightly and prevents leakage and also prevents leakage of the solution back into the atomizer bulb. The firm claims that the nozzle can be removed for sterilization and that the unit is economical and efficient. It is highly recommended by the company for use by those who travel extensively.

Several of these units were examined by consultants of the Council. Their findings were in agreement with the claims made by the manufacturers. The company declared

that no medicament of any kind is sold with the atomizer as part of the package.

The T J Leak-Proof Atomizer therefore is included in the Council's list of accepted devices.

SAMSON ULTRAVIOLET SUNLAMP, TYPE 140 A, NOT ACCEPTABLE

The Samson United Corporation, Rochester N. Y., manufactures a product known as the Samson Ultraviolet Sunlamp, Type 140 A. It is advertised to the public and profession in pamphlets containing statements such as "health and light in the same lamp," "prevention and cure of rickets and building sound bones and teeth."

In a laboratory acceptable to the Council, measurements were made on a Samson Ultraviolet Sunlamp, Type 140 A at distances of 30 inches (76 cm) and 24 inches (61 cm) from the front edge of the reflector. The lamp was operated with 115 volts A C (60 cycles) on the primary of the transformer under which conditions (the secondary output) the input through the lamp was 103 volts and 62 amperes. The transformer accompanying this lamp was noisy and became rather warm on continuous operation.

Under these operating conditions the ultraviolet radiant flux of wavelengths less than and including 3,130 angstroms in microwatts per square centimeter ($\mu\text{W}/\text{cm}^2$) was as follows:

Samson type 140 A = $15.5 \mu\text{W}/\text{cm}^2$ (at 30 inches)

Samson type 140 A = $21.6 \mu\text{W}/\text{cm}^2$ (at 24 inches)

The aforementioned values do not agree with the physical measurements submitted by the manufacturer of which part of the report reads "thus the erythemic efficiency (2804 to 3130 Å) of the Samson type 140 was 225 microwatts."

The firm's measurements appear to be the result obtained by integrating the radiant flux in all directions, whereas in the Council's opinion the profession and public are concerned only with the radiant flux at a specified distance below the lamp when it is in its reflector.

If this lamp is to comply with the specifications of minimum intensity (which, for this type of glow lamp amounts to an

erythemogenic equivalent of $108 \mu\text{W}/\text{cm}^2$) the Samson unit, type 140 A, it seems, would have to be operated at a distance of 10 to 11 inches to produce an erythema on the average skin in fifteen minutes. On the other hand, at a distance of 18 inches an exposure of about forty-five minutes would be required, and about one hour and twenty minutes at 24 inches.

The Samson United Corporation has not submitted evidence of animal experiments indicating that radiations from the lamp will cure or protect against rickets in rats or other rachitic animals under control. Furthermore, the firm has not submitted clinical or scientific evidence of any kind substantiating the therapeutic efficacy of the lamp.

Since the Samson Ultraviolet Sun Lamp, Type 140 A, does not meet the specifications of minimum intensity adopted by the Council on Physical Therapy and since the firm has failed to submit clinical or scientific evidence substantiating its therapeutic efficacy, the Council has omitted the Samson Ultraviolet Sunlamp, Type 140 A, from the list of acceptable devices for physical therapy.

Council on Pharmacy and Chemistry

REPORT OF THE COUNCIL

THE COUNCIL HAS AUTHORIZED PUBLICATION OF THE FOLLOWING
REPORTS

PAUL NICHOLAS LEECH Secretary

IODOCHLOROL AND IODOCHLOROL EMULSION NOT ACCEPTABLE FOR N N R

Iodochlorol is the proprietary name under which G. D. Searle & Co., Inc., market a preparation stated by the firm to be "an iodine and chlorine addition product of peanut oil containing 25 to 27 per cent of iodine and 67 to 76 per cent of chlorine in organic combination." The firm also markets Iodochlorol Emulsion, which is Iodochlorol in an emulsifying menstruum containing ethyl esters (unhalogenated) of peanut oil as a diluent. The product was presented for the Council's consideration as an iodized oil for roentgen diagnosis and for iodine medication.

The manufacturer claims that "Iodochlorol (Searle) is the first successful attempt to prepare a fatty oil, which contains beside iodine, also chlorine in appreciable quantities chemically combined." Mainly on this claim the firm asserted justification for the use of a proprietary name. It was pointed out to the firm that the Council at that time was considering an iodized rapeseed oil which also contained chlorine and that the literature showed that the studies on which this product was based antedated those claimed by Searle & Co. for its product. The firm was informed, therefore, that the Council could not recognize a proprietary name for this product but would give further consideration to it if it was submitted under nonproprietary names such as "Chloriodized Peanut Oil," "Chloriodized Peanut Oil Ethylated" and "Chloriodized Peanut Oil Emulsion." After a considerable correspondence, the firm still insisted that it deserved priority in the making of chloriodized oil and in effect insisted on retention of the proprietary name.

The Council therefore declared Iodochlorol (Searle) and Iodochlorol Emulsion (Searle) unacceptable for inclusion in New and Nonofficial Remedies because they are not entitled to proprietary names.

BISMOLD NOT ACCEPTABLE FOR N N R

Bismold is the proprietary name under which Eli Lilly and Company markets a product stated to be a stabilized suspension of finely divided bismuth, 25 mg per cubic centimeter in a sterile aqueous medium containing approximately 5 per cent of carbohydrate and glucose derivatives. The suspended matter is stated to contain at least 90 per cent of bismuth. It is proposed for use in the treatment of syphilis.

When the firm presented the product for consideration by the Council it submitted practically satisfactory experimental data consisting of toxicity and clinical tests on animals. No data based on the clinical use of the product in man has been

presented. The firm presented also advertising which the Council found, in some respects, objectionable. After consideration of the material submitted by the firm, the Council decided that the product was not yet ready for acceptance for New and Nonofficial Remedies but directed that the firm be informed that the Council would sponsor a preliminary report if the advertising was revised to meet stated objections and if the name was changed to the generic designation "Bismuth Metal Suspension (Aqueous)" in accordance with a report of the Council's Committee on Nomenclature, which found that the firm could not properly claim priority for this preparation. The Council stipulated the further condition that the product be found acceptable by the A. M. A. Chemical Laboratory. The Council voted also to postpone further consideration of the product until satisfactory clinical data were submitted.

Although Eli Lilly and Company, early in the Council's consideration of the product, had agreed to accept the proposed change of name, the firm later informed the Council that on account of objections by its sales division, the change could not be accepted. In view of this the Council was obliged, without further consideration of the claims for the composition of the product, to declare "Bismoid" unacceptable for New and Nonofficial Remedies because it is a preparation of bismuth without sufficient originality to justify the proprietary and insufficiently informing name under which it is marketed.

Committee on Foods

ACCEPTED FOODS

THE FOLLOWING PRODUCTS HAVE BEEN ACCEPTED BY THE COMMITTEE ON FOODS OF THE AMERICAN MEDICAL ASSOCIATION FOLLOWING ANY NECESSARY CORRECTIONS OF THE LABELS AND ADVERTISING TO CONFORM TO THE RULES AND REGULATIONS. THESE PRODUCTS ARE APPROVED FOR ADVERTISING IN THE PUBLICATIONS OF THE AMERICAN MEDICAL ASSOCIATION AND FOR GENERAL PROMULGATION TO THE PUBLIC. THEY WILL BE INCLUDED IN THE BOOK OF ACCEPTED FOODS TO BE PUBLISHED BY THE AMERICAN MEDICAL ASSOCIATION.

RAYMOND HERTWIG, Secretary

MEAD'S SOBEE

Manufacturer—Mead Johnson and Company, Evansville, Ind.

Description—An infant food preparation containing soy bean flour, olive oil, arrowroot starch, Dextri-Maltose (essentially maltose and dextrans), dicalcium acid phosphate and sodium chloride.

Manufacture—The soy bean flour ingredient is prepared from split and hulled soy beans, which are extracted with a fat solvent to remove most of the fat. The solvent is removed by evaporation in "vacuum." The resulting cake is ground to a flour.

Formula proportions of the solid ingredients are mixed with a suitable amount of water and cooked under low steam pressure, olive oil is added, the mixture is homogenized, dried in an atmospheric drum dryer and packed in cans.

Analysis (submitted by manufacturer) —

	per cent
Moisture	2.4
Ash	8.0

Lead (Pb)	less than 1.9 parts per million

Calories—4.5 per gram 128 per ounce

Vitamins—Vitamin B (complex), 85 Chick and Roscoe units per ounce

Claims of Manufacturer—A dietary preparation free from animal and milk protein for infants with milk idiosyncrasy.

SHENANDOAH APPLE SYRUP

SWEETENED WITH FRUIT SUGARS—INVERT SUGAR

Manufacturer—Ridgewood Fruit Growers, Winchester, Va.

Description—Syrup prepared from concentrated apple juice and cane sugar.

Manufacture—The juice is expressed by hydraulic pressure from ripe Virginia apples free from arsenical spray residues, as certified by the state department of agriculture. The juice is filtered. A definite proportion of sucrose is added and the sweetened juice is concentrated to approximately 72 per cent sugar content and packed in glass jugs. The malic acid inverts the added sucrose to invert sugar during the concentration.

BEECH-NUT PRESSURE COOKED FARINA CERE-JEL

(SLIGHTLY SEASONED WITH SALT)

Manufacturer—Beech-Nut Packing Company, Canajoharie, N. Y.

Description—Sieved cooked farina, seasoned with salt.

Manufacture—Farina is cooked for thirty minutes in water containing 0.5 per cent sodium chloride. The remainder of the process is the same as that for Beech-Nut Strained Carrots (THE JOURNAL, Nov. 11, 1933, p. 1562) except that the jars are processed for two to three hours at 104°C.

Analysis (submitted by manufacturer) —

Carbohydrates other than crude fiber (by difference)	9.3

Calories—0.4 per gram 11 per ounce

Claims of Manufacturer—Especially intended for infants, children and convalescents and for special smooth diets. Only warming is required for serving.

STOKELY'S FOR BABY SPECIALLY PREPARED STRAINED GREEN BEANS (ADDED SALT)

Manufacturer—Stokely Brothers & Company, Inc., Indianapolis.

Description—Strained green beans, seasoned with salt, retaining in high degree the natural vitamin and mineral content.

Manufacture—Fresh green beans are carefully inspected (imperfect ones eliminated), washed under high pressure water sprays, blanched a minimum time in boiling water, pressure cooked in an atmosphere of steam and comminuted in an atmosphere of steam by being forced through a fine screen to produce the desired texture. The strained material is adjusted with hot water to the desired consistency, slightly seasoned with salt, heated and filled into enamel lined cans which are sealed and heat processed.

Analysis (submitted by manufacturer) —

	per cent
Moisture	92.0

pH	5.2

Calories—0.2 per gram 6 per ounce

Vitamins—The natural vitamin content is retained in large measure in the manufacturing process by the use of equipment.

and procedure which exclude incorporation of air, the vegetable material is exposed to steam only

Claims of Manufacturer—Supplementary to the infant milk diet and valuable for children and adults on soft diets. Has smooth consistency and supplies desirable bulk without roughness. The straining renders the nutrient content readily available for digestion. Scientifically prepared to retain in high degree the natural flavor, mineral and vitamin values. Seasoned to bring out full flavor and packed in enamel lined cans. Requires only warming for serving.

- (a) LIBBY'S FANCY RED ALASKA SALMON
LIBBY'S ALASKA SOCKEYE SALMON
LIBBY'S FANCY BLUEBACK SALMON
(b) LIBBY'S CHINOOK ALASKA SALMON
LIBBY'S FANCY CHINOOK SALMON

Packer—Libby, McNeill & Libby, Chicago

Description—(a) Alaska Red or Sockeye Salmon and (b) Alaska King or Chinook Salmon

Manufacture—Salmon is rushed from the fishing nets to the cannery, inspected for elimination of bruised or deteriorated fish, conveyed to butchering machines, into tanks of flowing cold water, and to tables where the cleaning and inspecting operations are completed. The fish are again washed cleaned, automatically cut into proper lengths, and automatically canned with the addition of a definite amount of salt. The cans are sealed under a high "vacuum" and processed for ninety minutes at 116 C. The processing makes the fish ready to eat and softens the bone.

Vitamins—Fair, good and excellent source of vitamins A, G and D, respectively

BEECH-NUT TOMATO JUICE (SLIGHTLY SEASONED WITH SALT)

Manufacturer—Beech-Nut Packing Company, Canajoharie, N. Y.

Description—Tomato juice seasoned with salt (0.5 per cent), retaining in high degree the natural mineral and vitamin content.

Manufacture—Juice is expressed from carefully selected washed ripe tomatoes by a machine permitting minimum exposure to air, 0.5 per cent sodium chloride is added and dissolved air is removed by vacuumizing. It is heated to 82 C and filled into jars which are sealed under 'vacuum' and heated to 82 C for twenty minutes.

Analysis (submitted by manufacturer) —	per cent

Carbohydrates other than crude fiber (by difference)	5.8

Calories—0.2 per gram 6 per ounce

Claims of Manufacturer—The natural mineral and vitamin values are efficiently retained. Sealed under vacuum.

GOLDEN DRIP BRAND GOLDEN TABLE SYRUP

Distributor—Union Sales Corporation, Columbus, Ind.

Manufacturer—Union Starch & Refining Co., Granite City, Ill.

Description—A table syrup, corn syrup flavored with refiners' syrup.

Manufacture—Same as Pennant Golden Table Syrup. THE JOURNAL, Jan 30, 1932, page 403, excepting that less refiners' syrup is used.

Analysis (submitted by manufacturer) —	per cent
Moisture	25.5
Ash	0.7
Fat (ether extract)	0.0
Protein (N X 6.25)	0.1
Reducing sugars as dextrose	30.3
Sucrose (invertase method)	4.4
Dextrins (by difference)	19.0
Titratable acidity as HCl	0.04
Sulphur dioxide as SO ₂	0.002
pH	5.4

No methods are available for accurately determining the composition of syrups of this nature, therefore the foregoing analysis is roughly approximate.

Calories—3.0 per gram 85 per ounce

Claims of Manufacturer—For table use and as a carbohydrate supplement for milk modification in infant feeding.

STOKELY'S FOR BABY SPECIALLY PREPARED STRAINED PRUNES NO SEASONING ADDED

Manufacturer—Stokely Brothers & Company, Inc., Indianapolis

Description—Sieved prunes largely retaining the vitamins and all the natural minerals.

Manufacture—High grade medium sized prunes are carefully inspected to eliminate any unsuitable material, are washed under high pressure cold water sprays, are covered with a minimum amount of water, and the temperature is slowly raised to simmering and held there till the prunes are swelled and softened. The prunes and juice are drawn off and passed through a pulping machine to remove the pits, the mass is sieved through a fine screen, adjusted with hot water to the desired consistency, heated and filled into enamel lined cans, which are sealed and processed.

Analysis (submitted by manufacturer) —	per cent
Moisture	65.7
Total solids	34.3
Ash	0.9
Fat (ether extract)	0.04
Protein (N X 6.25)	1.2
Reducing sugars as dextrose	20.6
Sucrose	1.0
Crude fiber	0.8
Total acidity as malic acid	0.8
Pectin	2.1
Pentosans	1.1
Carbohydrates other than crude fiber (by difference)	31.4
pH	5.1

Calories—1.3 per gram 37 per ounce

Vitamins—The natural vitamin content is retained in large measure in the manufacturing process by the use of equipment and procedure which exclude incorporation of air, the fruit material is exposed to steam only.

Claims of Manufacturer—Supplementary to the infant milk diet and valuable for children and adults on soft diets. Has smooth consistency and supplies desirable bulk without roughness. The straining renders the nutrient content readily available for digestion. Scientifically prepared to retain in high degree the natural flavor, mineral and vitamin values. Packed in enamel lined cans. Requires only warming for serving.

TARTAN BRAND UNSWEETENED EVAPORATED MILK

Distributor—Alfred Lowry & Bro., Philadelphia

Packer—The Defiance Milk Products Co., Defiance, Ohio

Description—Unsweetered, sterilized, evaporated milk. The same as Defiance Pure Evaporated Milk, THE JOURNAL, March 3 1934, page 693.

HYPERPARATHYROIDISM A CHAPTER IN SUCCESSFUL LABORATORY RESEARCH

A stimulating record of clinical research, recently published in *THE JOURNAL*,¹ serves as an interesting reminder of how effectively some of the disconcerting manifestations of disease and the "pathologic curiosities" of practical medicine are being explained by improved procedures in laboratories of medicine. To many it may seem strange that in this day "laboratory medicine" needs any apologies or defense. Yet not long ago Mendel² of Yale University said that there are today not a few physicians as well as other friends of medicine who although admitting the noteworthy contributions of animal experimentation, nevertheless urge that its dominant importance is passing. Though the pendulum of enthusiasm for a laboratory innovation may at times swing too far, it soon reaches a stable level. In his defense of scientific experimentation in medicine, Mendel made a vigorous plea that devotees of practical medicine and surgery refrain from unwarranted derogatory attacks on one of the best helps of their profession in the past. It is difficult enough, he added, to fight suffering, disease and death without being obliged to fight the ignorance and prejudices of those who would tie the arms of the laboratory worker. The ultimate objective of all methods of attack on ignorance is the same.

Osteitis fibrosa cystica, commonly called von Recklinghausen's disease, has long been recognized as a chronic progressive disease of the skeleton. One will look in vain for any rational or well founded discussion of its etiology and treatment in all except the most recent textbooks, for it was not until the present decade that the relation of the malady to hyperparathyroidism was clearly established, through the classic observations of Mandl³ in Vienna and Du Bois⁴ and his co-workers

in New York. Only a few years ago less than 100 cases of von Recklinghausen's disease had been mentioned in medical literature. The report of Albright, Aub and Bauer¹ presents seventeen proved cases of hyperparathyroidism from a single clinic in the Massachusetts General Hospital in Boston.

What are the main features of the newer knowledge? Foremost is the observation that hyperparathyroidism is usually due to a functioning adenoma of the parathyroid glands. Sometimes there is hyperplasia of all parathyroid tissue. As a result of the increased production of the parathyroid hormone there is a disturbance in the metabolism of calcium and phosphorus. The easily measurable manifestations of this disturbance are an increased serum calcium level, a decreased serum phosphorus level and an increased excretion of both elements in the urine. The ascertainment of these diagnostic features has depended on the discovery of the endocrine function of the glands involved, on methods for the ready clinical estimation of calcium and phosphorus in readily obtained small specimens of blood, on the unraveling of the fundamental features of replacement therapy and dietary control. Every detail of these highly significant and frequently life-saving factors has emanated from the scientific laboratories through the laborious and modest efforts of persons who are sometimes referred to somewhat disparagingly as "research hounds." One may recall that the epithet "book farmer," similarly applied to progressive students of agriculture a generation ago, has long since been abandoned.

The relations of parathyroid function to calcium and phosphorus may bring the reminder that about 85 per cent of the mineral matter of bone, or at least three fourths of the entire ash of the body, consists of calcium phosphate. Probably more than 99 per cent of the calcium in the body belongs to the bones, the remainder occurring as an essential constituent of the soft tissues and body fluids. That is why any influence such as hyperfunction of the parathyroids with its attendant hypercalcemia leads so characteristically to demineralization of the bones. They become porous and filled with osteoclasts. There are drastic secondary consequences. The increased mobilization and excretion of calcium and phosphorus in the urine not infrequently lead to the formation of urinary calculi. In some instances the calcium phosphate precipitates occur in the kidney parenchyma and lead to secondary kidney contracture and insufficiency.⁵ Again, the replacement of so much of the marrow cavity with fibrous tissue leads to a decrease in the hematopoietic elements and hence occasionally to an anemia and leukopenia.

Despite the fact that the bones are the storehouse for calcium and phosphorus in the body, according to

Albright, Aub and Bauer, the teeth do not take part in the generalized decalcification. They may fall out because of disease of the jaws, but they themselves remain well calcified. This is brought out strikingly by roentgenograms in which the well calcified teeth stand out sharply against the poorly calcified jaws. This failure of the teeth to become decalcified is featured as strong evidence against their being a reserve supply of calcium.

The management of the parathyroid tumors presents a real challenge to the modern surgeon. As Albright, Aub and Bauer say, before undertaking an operation he must be more than just "a good thyroid surgeon." He should know the normal and possible aberrant situations of the parathyroid glands, he must be familiar with their reddish brown coloration and smooth surface (in contrast to the granular surface of the thyroid), he must be able to differentiate them from lymph nodes, collections of fetal fat and thyroid lobules, and he must be prepared to continue the search, even if this leads him into the anterior mediastinum. For the latter reason the surgeon must not undertake the operation until he is convinced by the blood chemistry that a tumor is present. There is no time like the initial operation to find the tumor. The hypoparathyroidism following the removal may be dangerous, with its attendant tetany. A dietary regimen including calcium and phosphorus in abundance may prevent decalcification and thus improve the bones, yet may need to be avoided because of the possibility of renal damage. These features suffice to indicate the acumen and modern knowledge that are requisite for the management of hyperparathyroidism. The Boston investigators stress the point that, whereas the disease can hardly be called common, it must frequently be considered when any of a multiplicity of symptoms is present. Failure to make the diagnosis is regrettable in that the treatment for it is highly successful.

PSITTACOSIS

Although psittacosis was known prior to 1929, the epidemic of that year and the attendant publicity brought the disease to the attention of almost every physician and health officer in the country. There have been repeated occurrences during the intervening years, but the fact that the mode of transmission of the disease and the susceptibility of various species have been discovered and practical methods of control have been instituted indicate that progress has been made in the attempt to eliminate it as a factor in our national health. Indeed, a recent report describes the successful vaccination of human patients against the disease. The present status of psittacosis from various points of view has recently been summarized by Hoge.¹ The incidence of the disease is generally

decreasing, whereas in 1932 there were seventy-six cases and seven deaths, in 1933 only fifteen cases, of which four were fatal, came to the attention of the authorities. This year, however, up to the middle of March, twenty-seven cases and eleven deaths were recorded. As the epidemic of 1929-1930 was shown to have its origin in infected parrots, the disease was called "parrot fever." It has been demonstrated, however, that the most important vector of psittacosis is the shell parakeet, principally because this bird enters into commerce in large numbers. On the other hand, it is known that all or nearly all birds belonging to the family Psittacidae are actual or potential carriers of the disease. Up to the present, a large proportion of the human cases of psittacosis have occurred in California. This circumstance is correlated with the widespread occupation of breeding and rearing psittacine birds in that state. The fact that all reported human cases of the disease occurring in the United States have been traced to California-bred birds indicates the importance of strict control of the aviaries in those sections where the climate is favorable to the rearing of these birds.

Psittacosis is caused by a filtrable virus that appears to be readily passed from an infected bird to a healthy one, young birds being more susceptible than old birds. Apparently the virus can pass from birds to man by direct contact or through the lungs. The period of incubation is usually about twice as long in the birds (approximately fifteen days) as in human patients, in man the disease simulates pneumonia but with a marked dissociation of pulse rate and temperature. The virus can usually be demonstrated in the sputum and, when injected into mice, produces the disease in these animals. In the tissues of man, mice and bird with psittacosis there usually occur the so-called L. C. L. bodies, which can be stained and observed microscopically and which may be one form assumed by the virus in a developmental cycle.

Psittacosis presents a unique problem in public health control. On the one hand, the known facts definitely connect the presence of infected psittacine birds with the spread of the disease to human beings. On the other hand, the fact that most of those rearing birds are in business in a small way, together with the hesitation in accepting advice resulting in financial loss, has rendered regulation difficult. However, certain states and Hawaii have already prohibited the importation of parakeets. As it has been found that psittacosis is endemic in California aviaries, both federal and state regulations have been formulated to permit the shipment only of birds that are certified to be free from the disease by the state health officer.

Despite the difficulties arising from lack of fundamental knowledge of the disease as well as from opposition to regulation, the results of the efforts to control psittacosis have been favorable. However, there is presented here a situation of extremely grave

¹ Hoge, V. M. Pub. Health Rep. 49:451 (April 6) 1934.

possibilities Hoge states that "few diseases can claim a more diversified list of susceptible species" Recently the chicken has been shown to be susceptible to the disease both by inoculation and by feeding infected material The widespread use of poultry as human food and the necessary contact with chickens in the egg industry emphasize the great potential danger from this source alone The accumulating facts indicate that in uncontrolled psittacosis there exists a serious menace both to the public health and to commerce

ARTIFICIAL RESPIRATION MAINTAINED FOR TWO YEARS

In this day of complex mechanical devices for the care of the sick, it is refreshing to observe that the simple things at hand sometimes serve the purpose well A unique example is found in a case of progressive muscular atrophy, recently reported by Kerridge,¹ in which artificial respiration has been maintained for two years A man, aged 63, gradually lost control of various groups of muscles until he was unable to breathe without assistance In the first serious attack of difficult breathing, which occurred when he was riding in a car, he was relieved by companions pressing rhythmically on the front of his chest From this time he was treated by his family in the same way, whenever respiratory difficulty recurred The attacks gradually lengthened and in less than a year he was having artificial respiration performed continuously day and night by relatives and nurses Sir William Bragg, the physicist, a friend of the patient, suggested bandaging a football bladder to the patient's chest and connecting it through a rubber tube to another bladder fixed between two hinged boards so that it could be moved rhythmically by the foot or with a lever This apparatus was effective, but the bladders wore out in three days They were replaced by a hot water bottle, which lasted three weeks, when it had to be patched or replaced The boards were used until the hinges wore loose A more substantial apparatus made on the same principle proved to be too hard for the nurses to operate Then a small hydraulic machine was constructed, worked off the main water supply, which alternately compressed and relaxed a rubber bellows—except on one occasion when the water froze in the pipes This apparatus has been keeping the patient alive since October 1933 For a few hours each day, the manual method of artificial respiration is used to relieve the constriction of the bandage about the patient's chest Recently Kerridge has replaced the hot water bottle and binder by a linen belt interlined with a bag of rubber of a size to surround the front and back of the left side of the chest The patient has worn this apparatus comfortably and continuously for weeks A pressure in the bag of nine-tenths pound per square inch, produced twenty-two times a minute, has been sufficient This almost completely paralyzed

patient is active mentally, although wasted He lies on his right side almost continuously His appetite is good There have been no bed sores When artificial respiration was stopped for one minute, movement did not occur in the thorax or diaphragm Prior to the development of progressive muscular atrophy, the patient led an active outdoor life and had no serious illness This interesting case shows that positive pressure can be used without apparent ill effects for a long time A striking feature of the case, which Kerridge notes, is the comfort of the patient and the simplicity of the mechanism used The patient carries on his normal intellectual pursuits at home In this issue of *THE JOURNAL*, some papers presented at the second annual meeting of the Society for the Prevention of Asphyxial Death are abstracted The case report by Kerridge casts a bright glow on the great field in life saving which that society has undertaken to illuminate

THE INORGANIC STRUCTURE OF BONE

The biochemist's conception of the nature of bone and related structures has been developed to an increasingly clear understanding in recent years The definition of bone as a tissue consisting of water and about equal parts of organic and inorganic material has become obsolete The inorganic constituents of bone can be regarded as consisting almost entirely of a mixture of calcium phosphate and carbonate, in the proportion of three to (somewhat less than) one, built together into some complex along with traces of the corresponding magnesium compounds and of chloride and fluoride No definite clue to the constitution of this complex has as yet been obtained, though the proportions of the constituents are constant¹ By roentgen examination and by chemical analysis it seems to be similar, as far as its inorganic constituents are concerned, to the mineral dahllite, though there is no complete agreement on this feature The application of x-ray diffraction methods, which have afforded so much new information in other fields of scientific research seems destined to extend the knowledge of the structure of bone not only in health but also in disease of the osseous tissues Janet H. Clark² of Johns Hopkins University has produced x-ray diagrams of bones and teeth She believes that inorganic crystals of apatite are present in bone oriented so as to give fiber structure in longitudinal section There are also nonoriented crystals present which are attributed to organic crystals of collagen or ossein In a more recent study, by Clark and Mrgudich³ of the Department of Chemistry at the University of Illinois, the longitudinal orientation of the inorganic micelles of bone has been confirmed In rickets this preferred orientation seems to be to a large extent destroyed The Illinois observers look on the attack of rickets as a breaking down of the organic "cement" (collagen or

¹ Kerridge, Phyllis M. Tookey. Artificial Respiration for Two Years. *Lancet* 1: 786 (April 14) 1934

¹ Cameron, A. T. A Textbook of Biochemistry. New York, Macmillan Company, 1933

² Clark, Janet H. A Study of Tendons, Bones and Other Forms of Connective Tissue by Means of X-Ray Diffraction Patterns. *Am. J. Physiol.* 98: 328 (Sept.) 1931

osseous) which holds the inorganic crystals in their normal oriented position. After this 'cement' has been decomposed the inorganic material, although remaining chemically unchanged, loses its preferred orientation and the bone loses its resistance to strain in much the same manner as a tied bundle of sticks loses its supporting strength when untied and scattered. On healing, the inorganic micelles of a rachitic bone do not regain their preferred orientation, although the organic constituent assumes the same form as in the normal bone. Clark and Mrgudich conclude that any theory involving equilibrium between serum calcium and bone calcium must take into account the more fundamental equilibrium between serum and the organic constituent of bone.

Association News

THE CLEVELAND SESSION

Visit to Home of George Edward Follansbee

The home of Dr. and Mrs. George Edward Follansbee will be open to visiting women guests at the American Medical Association convention at Cleveland on Tuesday, Wednesday and Thursday afternoons of the convention week from 2 to 5 p. m. Visitors will enjoy Mrs. Follansbee's nationally famous collection of Americana. Tea will be served.

Guests desiring to visit the Follansbee home will be expected to leave notification at the women's registration desk in the Hotel Carter.

Golf for Pediatricians

Members of the Section on Pediatrics are urged by the Cleveland committee to bring their golf clubs. A special event has been scheduled for the members of the section at the Country Club. Details will be announced at the section meetings.

Rotary Club Luncheon

The regular luncheon of the Cleveland Rotary Club will be held Thursday noon, June 14, in the Rainbow Room of the Hotel Carter. All Rotarians are invited to attend.

Railroad Rates

The Transcontinental and Western Passenger Associations state that fare and one third of the current one-way first class fares is lower than summer excursion fares from New Mexico and that selling dates of tickets from New Mexico will be June 4 to 12 inclusive.

MEDICAL BROADCASTS

National Broadcasting Company

The American Medical Association broadcasts on a coast-to-coast network each Monday afternoon from 3:45 to 4 o'clock, Central daylight saving time (3:45 Eastern standard time, 2:45 Central standard time, 1:45 Mountain standard time and 12:45 Pacific standard time).

The next three broadcasts will be as follows:

May 28 The Family Medicine Chest Morris Fishbein M.D.
June 4 Highway Hazards W. W. Bauer M.D.
June 11 The Common Cold Wilson G. Smillie M.D. (from Cleveland)

The National Broadcasting Company talks will be discontinued for the summer with the talk from Cleveland on June 11.

Columbia Broadcasting System

The Association broadcasts on a Western network of the Columbia Broadcasting System each Thursday afternoon on the Educational Forum from 4:30 to 4:45 Central daylight saving time. The June 14 broadcast will be from Cleveland at 4 to 4:15 p. m., Eastern daylight saving time. The next three broadcasts will be as follows:

May 31 Health Slogans W. W. Bauer M.D.
June 7 The First Month W. W. Bauer M.D.
June 14 Medicine Marching Forward Morris Fishbein M.D.

ALABAMA

Clinical Meeting—Dr. Joseph H. Griffin, Bainbridge, Ga., was elected president by the John A. Andrew Clinical Society at its twenty-third annual clinic at Tuskegee Institute, April 8-14. Papers were presented by the following physicians, among others:

Richard H. Miller, Boston, Diagnosis of Acute Abdominal Emergencies
Thomas M. Smith, Chicago, Coronary Occlusions
James L. Hall, Chicago, Intestinal Parasites and Infections
Roman T. Adair, Montgomery, Diagnosis and Treatment of Bronchial Asthma
Roscoe C. Giles, Chicago, Diagnosis and Treatment of Osteomyelitis
Walter G. Crump, New York, Science of Medicine As It Is Related to the Art of Medicine
Ralph H. Scull, Chicago, Common Fungus Diseases of the Skin and Preliminary Report on Work Done with Trichophyton at Rush Medical College
Alan P. Smith, Jr., Tuskegee, Syphilis of the Parenchyma of the Brain
John E. Hunter, Lexington, Ky., Intestinal Obstruction
Lee O. Miller, Asheville, N. C., Reduction of Blood Pressure Without Injury
Clarence Leon Wilson, Chicago, Sterility in the Female: Etiology, Diagnosis and Treatment
Ulysses G. Dailey, Chicago, Present Status of Treatment of Hyperthyroidism
John W. Chenault, Chicago, Intervertebral Disk and Spinal Disabilities
Willard M. Lane, Washington, D. C., Appendicitis, with Special Reference to the Disease in Women
John H. Hale, Nashville, Tenn., Rupture of the Meningeal Artery with a Depressed Fracture of the Brain
Frank Jones, Washington, D. C., A Case of Nephrobronchial Fistula and a Case of Elephantiasis of the Scrotum Due to Filaria Bancrofti
Henry A. Calhoun, Washington, D. C., Dehydration
Toussaint T. Tilden, Tuskegee, Ala., Spontaneous Cardiac Rupture, with Report of Case

Clinics and demonstrations in the various specialties were conducted.

ARKANSAS

Society News—At a meeting of the Benton County Medical Society in Siloam Springs, March 8, speakers were Drs. Davis W. Goldstein and James C. Ogden, Fort Smith, on 'Malignancies of the Skin' and 'The Eye in Relation to General Medicine,' respectively. Among others, Dr. Johnson J. Baker, Magnolia, spoke before the Sixth Council District Medical Society in Texarkana, March 8, on 'Treatment of Malaria Other Than Quinine.' Speakers before a joint meeting of the Sebastian and Jasper County medical societies, March 13, included Dr. Samuel A. Grantham, Joplin, Mo., on a method of spinal fusion. The Second Council District Medical Society was addressed in Batesville, April 15, among others, by Drs. Wells F. Smith, Little Rock, and Martin C. Hawkins, Jr., Searcy, on traumatic epilepsy and uterine bleeding, respectively.

CALIFORNIA

The Health Insurance Racket—A charge of selling insurance without a permit against John C. Moore, San Francisco, head of one of the racketeering health insurance associations in California, was dismissed, April 24, on the grounds of insufficient evidence. The state board of medical examiners was not consulted when Moore's trial was called, and it was held when the special investigator for the board was out of town. Moore operated the 'Pacific International Health Association' at 127 Montgomery Street, San Francisco. This organization had previously been known as the International Metropolitan Health and Accident Association but was changed following the objection by the Metropolitan Life Insurance Company to the word 'Metropolitan.' An application given by Moore to the investigator for the board read 'United States Agency—Pacific International Health Association—medical-surgical-dental-hospital-ambulance-laboratory-optometry services—Emergency Expense—Life—Accident—Health Protection.' It purports to offer medical and surgical benefits 'by any duly licensed physician in any sickness or accident.' According to the state medical board, investigation indicates this to be 'sales talk,' because when the purchaser receives his contract, it is said to specify therein that the professional service to which he is entitled is limited to a physician chosen by the company. It is pointed out that a holder of a contract as a complainant, having accepted it, is precluded from bringing in as evidence the application which he signed should he begin any legal

action. He is further penalized because that portion of the application which he signs is immediately torn from the other portion of the application so that, in case of controversy, it is later impossible to connect the promises made in the application with the phraseology of that portion of the contract which has been signed by the applicant. Harry Kramer, head of five of these health associations recently received a sentence of from one to two years in San Quentin Prison and a fine of \$5,000 (THE JOURNAL, March 28, p. 1091).

COLORADO

Clinic for Venereal Diseases—The Pueblo County Medical Society recently appointed a committee on venereal diseases to educate the public to the need of a free clinic for the treatment of these diseases. About a year ago the state venereal clinic, administered by the state health board, was discontinued in Pueblo and other cities of the state thus putting an end to the supervised treatment of these patients. It is hoped that the committee's work and public opinion will bring about the establishment, by legislative action, of one health board with definite duties not only for the treatment of the indigent, but for the entire public health problem. It was pointed out that until this is assured the Child Welfare and Public Health Association of Pueblo will endeavor to seek county and community chest funds to continue the free clinic.

DELAWARE

Health at Wilmington—Telegraphic reports to the U. S. Department of Commerce from eighty-six cities with a total population of 37 million for the week ended May 12 indicate that the highest mortality rate (186) appears for Wilmington and that the rate for the group of cities as a whole was 119. The mortality rate for Wilmington for the corresponding week of last year was 166, and for the group of cities, 108. The annual rate for eighty-six cities for the nineteen weeks of 1934 was 125, as against a rate of 119 for the corresponding period of the previous year. Caution should be used in the interpretation of these weekly figures, as they fluctuate widely. The fact that some cities are hospital centers for large areas outside the city limits or that they have a large Negro population may tend to increase the death rate.

DISTRICT OF COLUMBIA

Medical Bills in Congress—S. 3479, proposing to amend the healing arts practice act of the District of Columbia, has been reported to the Senate, without amendment (S. Rept. 990). The bill would amend the existing law (1) by substituting the corporation counsel of the District of Columbia for the United States district attorney as a member of the Commission on Licensure to Practice the Healing Art and (2) by transferring to the corporation counsel for the District of Columbia, from the United States district attorney, the duty of instituting legal proceedings for the enforcement of the act.

ILLINOIS

Society News—Dr. William C. Danforth, Evanston, Ill., addressed the Vermilion County Medical Society in April on "Symptoms and Treatment of Fibroids."—At a meeting of the Madison County Medical Society in Madison, April 6, Dr. Lee Pettit Gay, St. Louis, spoke on allergy.—Speakers before the Douglas County Medical Society April 28, included Drs. Don W. Deal on acute conditions of the abdomen, Hermon H. Cole, prevention of heart disease and Walter G. Bain, general relation of sinuses and chest conditions. All are from Springfield.—Dr. Max Thorek, Chicago, addressed the Warren County Medical Society at Monmouth May 2, on "An Electrosurgical Method of Obliterating the Gallbladder."

Chicago

Hospital News—The cornerstone of the new \$1,000,000 Chicago Polyclinic Hospital was laid, May 11. The institution, formerly known as Henrotin Hospital, will be six stories high with a capacity of 100 beds. The old hospital was erected in 1907.

Alumni Reunion Rush Medical College—The annual reunion of Rush Medical College will be held in Chicago June 8 and 9, in order to permit visiting alumni to attend this reunion and to go to the annual meeting of the American Medical Association in Cleveland the week following. Special clinics will be held for the visiting alumni on June 8 and 9. The annual banquet of the Rush Faculty and Alumni will be held at 6:30 Saturday evening, June 9, at the Palmer House. Special class reunions of the tenth, twentieth, thirtieth, fortieth and fiftieth year classes will be held Friday evening, June 8, at the Palmer House.

IOWA

Society News—The eighth Iowa Conference on Child Development and Parent Education will be held in Iowa City June 19-21. Dr. William E. Blatz, director, St. George's School of Child Study, Toronto, Canada, will be among the speakers. Details may be obtained from the Iowa Child Welfare Research Station, State University of Iowa, Iowa City.—The Cerro Gordo County Medical Society was addressed, May 14, by Dr. Verne C. Hunt, Los Angeles, on "Cancer of the Breast."—Dr. James W. Young, Newton, discussed socialized medicine before the Jasper County Medical Society in Newton, April 3.—At a meeting of the Jefferson County Medical Society, April 18, Dr. Robert O. Hughes, Ottumwa, spoke on diagnosis of diseases of children.—The Johnson County Medical Society was addressed, April 4, by Dr. Harry L. Alexander, St. Louis, on "Allergy from the Standpoint of the General Practitioner."—Dr. Charles B. Taylor, Ottumwa, was guest of honor at a meeting of the Keokuk County medical and dental associations, April 16, in Sigourney. The guest speaker was Ralph A. Fenton, DDS, Iowa City, on "Focal Infections."—Dr. Jack V. Treynor, among others, addressed the Pottawattamie County Medical Society in Council Bluffs April 26 on "Indications for Tracheotomy."—At a meeting of the Scott County Medical Society in Davenport, Dr. David S. Hilts, Chicago, discussed obstetrics and the general practitioner.

KENTUCKY

Extension Course in Russellville—Drs. Malcolm D. Thompson and Winston U. Rutledge, Louisville, were the lecturers in an extension course under the auspices of the Kentucky State Medical Association at Russellville, May 9, with the Logan County Medical Society as host. Dr. Rutledge discussed dermatologic subjects and Dr. Thompson, treatment of injuries.

Dr. Jones Returns to Utah—Dr. John L. Jones, Louisville, director of the bureau of epidemiology of the state board of health for the past six years, has resigned to become assistant health officer of Utah, his native state. Dr. Jones was honored with a farewell dinner at the Pendennis Club April 24, at which guests included the staff and members of the board of health and representatives of county health departments, the city health department, medical societies and auxiliaries. Dr. Arthur T. McCormack, state health officer, presided and addresses were made by Drs. Hugh R. Leavell, city health commissioner, John D. Trawick, county health officer, Louis Frank, Philip F. Barbour, all of Louisville. Dr. Robert H. Crowley, Berea, and Dr. Jones. A silver service was presented to Dr. and Mrs. Jones. Dr. Martin H. Jensen, formerly assistant director of the bureau of county health work, has been appointed to succeed Dr. Jones.

MARYLAND

State Medical Election and Meeting—Dr. John M. T. Finney, Baltimore, was elected president of the Medical and Surgical Faculty of Maryland at its one hundred and thirty-sixth annual meeting in Baltimore April 24-26. Vice presidents elected are Drs. Louis Hamman, Baltimore, James McFadden Dick, Salisbury, and Victor D. Miller, Hagerstown. Dr. Walter D. Wise, Baltimore, was reelected secretary and Dr. Charles Emil Brack, Baltimore, was reelected treasurer. Dr. George O. Sharrett, Cumberland, delivered his address as retiring president on "Our Duty and Responsibility." The Trimble lectures were presented by Dr. John A. Kolmer, professor of medicine, Temple University School of Medicine, Philadelphia, on "Etiology, Diagnosis and Treatment of Septicemia," and Dr. Fred W. Rankin, Lexington, Ky., "The Development of Surgery of the Colon and Rectum." Other speakers on the scientific program included:

Dr. William H. Pearce, "The Sphere of State Medicine."
Dr. Cyrus F. Horine, "Distribution of Physicians in Maryland Counties."
Dr. Max Kahn, "Irradiation of Radiosensitive Tumors."
Dr. Dean Lewis, "President American Medical Association, Diagnosis and Prognosis of Gastrointestinal Tumors."

A round table luncheon was held, April 25, and included among others, the following speakers: Drs. Charles R. Austrian and "Pneumonia," Maurice C. Pincoffs, "Hyperthyroidism and Hypothyroidism in Relation to the Heart," "Recent Use of Thyroidectomy in the Therapy of Chronic Heart Disease," Esther L. Richards, "Strains of Life in Relationship to Nerves," and Other Forms of Poor Mental Health, and Henry J. Walton, "Educational and Professional Aspects of the Practice of Radiology."

New Marine Hospital—A new U S Marine Hospital was recently dedicated at Baltimore. Influenced by the design of the Johns Hopkins University group of buildings, the architecture generally follows the Georgian style. A dark granite base is used for the main buildings with rusticated limestone courses between the first and second floors. The other exterior facing is of sand finish red colonial brick in a full range of color with limestone trim. Black granite was used at the three main entrance doorways with bronze exterior bracket lamps. The interior of the main building is of typical hospital finish. Administrative offices, the pharmacy, eye, ear and nose clinic, clinical laboratory, staff room and hospital library are located on the first floor of the transverse wing while on the first floor of one of the lateral wings is the dental department and in the other, small isolation wards. On the first floor of the central wing are located the physical therapy and roentgen-ray departments. On the second floor of the transverse and lateral wings are located wards and private rooms, together with professional and administrative facilities and the basal metabolism section. This floor is for medical patients only. The second floor of the central wing contains the kitchen and dining rooms. The third floor of the transverse and lateral

I Weiner has resigned as medical director of the Oakland County Tuberculosis Sanatorium, Pontiac, on account of ill health.—Dr William E McNamara, Lansing, was recently named a member of the state council of health.

District Conference—The Michigan State Medical Society, and the department of graduate medicine of the University of Michigan conducted a conference in the fourteenth councilor district in Adrian, May 10, when the following program was presented:

Prevention and Repair of Birth Injuries to the Mother, Dr Howard H. Cummings, Ann Arbor
Differential Diagnosis in Acute Abdominal Disease, Dr Eugene B. Potter, Ann Arbor
Diagnosis and Treatment of Pneumonia, Dr Edward D. Spaulding, Detroit
Recognition and Management of Speech Defects, Prof John R. Mjuskens, Ann Arbor

Society News—The committee on preventive medicine of the Michigan State Medical Society presented the program before the Gogebic County Medical Society at its meeting in Ironwood, May 10, the program of the state medical society, its general principles and applications to counties were discussed by Dr Ledru O. Geib, Henry F. Vaughan, Dr P. H. Detroit, and Dr Garner M. Bjington, Battle Creek. Dr John E. Gordon, Detroit spoke on 'Differential Diagnosis in the Acute Communicable Diseases'.—Dr Claire L. Straith, Detroit, discussed 'Correction of Facial Injuries and Deformities' before the Livingston County Medical and Dental Society, May 4.—A symposium on diseases of the blood-forming organs was presented at Harper Hospital, Detroit, May 18, by Drs Russell L. Haden, Cleveland, Raphael Isaacs, Ann Arbor, and Hugo A. Freund, Detroit.

MINNESOTA

"Bone-Setters" Warned to Stop Practicing—The state board of medical examiners has issued a warning to three unlicensed practitioners of healing, so-called bone-setters, that they are to cease their activities unless they are registered under the Basic Science Law and licensed to practice. These men are P. D. Heppner, Butterfield, Claus Hiebert, Bingham Lake, and Jacob Goertzen, Mountain Lake. The board asks that any case of treatment subsequent to March 17 by any of these persons be promptly reported to the board at 524 Lowry Medical Arts Building, St. Paul, and action will be taken to force a compliance with the laws of Minnesota.

Society News—Speakers before the Hennepin County Medical Society, April 11, were Drs. Edward D. Anderson and Paul W. Gessler on 'Relationship of the Physician to the Handicapped Child' and 'Adjusting the Crippled Child to His Environment' respectively. Dr. Henry Schmitz, Chicago, addressed the society, May 7, on 'Early Diagnosis and Treatment of Uterine Carcinoma'.—Dr. Thomas B. Magath, Rochester, Minn., was elected president of the Minnesota Academy of Medicine at its second annual meeting in Rochester, April 21. Walter A. Kenyon, Ph.D., St. Paul, vice president, and Harold K. Wilson, Ph.D., St. Paul, reelected secretary.—Speakers before the Camp Release Medical Society at Dawson April 6, were Drs. Thurston W. Weum, Minneapolis on obstetrics, Myron O. Henry, Minneapolis, fractures, and Charles Bolsta, Ortonville, enforcement of the basic science law.—Dr. Hugh Cabot discussed 'Wartime Reminiscences of the Royal Army Medical Corps' before the sixteenth semiannual meeting of the Minnesota Society of Internal Medicine at Rochester, April 23.

MISSOURI

Personal—Dr. Herluf G. Lund, St. Louis, was presented with a gold watch at a buffet supper given in his honor April 6, at the Lenox Hotel, to mark his completion of twenty years as chairman of the staff of Lutheran Hospital. Dr. Theodore P. Brookes presided and the presentation was made by Dr. Phelps G. Hurford.

Society News—Members of the staff of the St. Louis City Hospital presented the program before the St. Louis Medical Society, May 15. Drs. Arthur A. Hines, "Preparation of Psychotic Patients for Spinal Puncture with Sedative Medication," James M. Macmish, "Cysto-Urethrography in the Male" and James M. Coleman "Hypersensitization"—"Necrotizing Ulcerations Complicating Erysipelas" was discussed before the Jackson County Medical Society, May 1, by Drs. Paul F. Stookey, Caryl R. Ferris, Hubert M. Parker and Louis A. Scarpellino. At a meeting of the society, May 15, Dr. Thomas G. Orr, Kansas City among others discussed the "Action of Morphine on the Intestinal Tract with Its Clinical Application".—Dr. George

New U S Marine Hospital at Baltimore

wings are for surgical patients. The fourth floor of the transverse and lateral wings is used for patients with genito-urinary and venereal diseases. The fifth and sixth floors of these wings are to be utilized for surgical and medical cases, while the seventh floor of the transverse or main wing will be nurses quarters. The central wing of the basement is used in part for a morgue and autopsy section.

MASSACHUSETTS

Safety Conference—The first annual New England Safety Conference convened at the Statler Hotel in Boston April 30-May 1. Included among the speakers on topics of medical interest were Dr. Robert S. Palmer of Harvard Medical School, Boston, Arthur B. Lamb, director, chemical engineering, Harvard University, Dr. Alton S. Pope, director, division of tuberculosis, Massachusetts State Department of Public Health, Dr. Timothy Leary, medical examiner of Suffolk County South, Theodore F. Hatch and Philip Drinker, of the faculty of the Harvard School of Hygiene and Public Health.

Society News—Dr. Alfred Stengel, Philadelphia, conducted a clinic on pneumothorax in the treatment of pneumonia, April 26, at the Peter Bent Brigham Hospital, Boston.—At a meeting of the Massachusetts Psychiatric Society in Boston, April 20, the speakers were Drs. Julius Loman, Boston, and Clifford D. Moore, Waltham on 'Effects of the Alteration of Posture on the Cerebrospinal Fluid Pressure' and 'Mental Disease in a Tuberculosis Sanatorium Population'.—Dr. Abraham Myerson, Boston addressed the Hampden District Medical Society in Springfield April 24 on 'The Neuroses as the General Practitioner Meets Them'.—At the annual meeting of the Worcester North District Medical Society in Fitchburg, April 25, Dr. Andrew R. MacAusland, Boston gave the annual oration on 'Recent Trends in the Treatment of Fractures'.

MICHIGAN

Personal—Dr. William M. Donald has been made head of the department of medicine of Wayne University School of Medicine, Detroit.—Dr. John J. Prendergast Jr., Detroit, has been named acting superintendent of Receiving Hospital, Detroit, succeeding Dr. Egil T. Olsen resigned.—Dr. Walter

Gellhorn, St. Louis, addressed the Kansas City Obstetrical and Gynecological Society, May 3, on "Local Anesthesia in Obstetrics and Gynecology."—Dr. Raymond E. Teall has been elected president of the Kansas City Society of Ophthalmology and Otolaryngology, and Dr. Andrew W. McAlester III, secretary.

NEW MEXICO

Health Survey Concluded—A health survey of New Mexico sponsored by the New Mexico Tuberculosis Association and directed by Carl E. Buck, Dr. P. H., of the American Public Health Association, was concluded April 30. A special survey of syphilis in one district was made under the auspices of the American Social Hygiene Association, and blood examinations were made by the survey staff in all the districts visited. Among other results it was found that active syphilis appears to be about twice as common as active tuberculosis. The morbidity rate of active adult tuberculosis is about twice as high among Anglo-Americans as among Spanish Americans, but the childhood type is twice as high among the Spanish American school children, as revealed by the Mantoux test. Special eye examinations showed that 85 per cent of school children had subnormal visual acuity and other symptoms of eye difficulty. The most frequent diseases of the eyes encountered among school children were folliculosis, in 54 per cent, conjunctivitis, 31 per cent, blepharitis, 1 per cent. Muscle imbalance was noted in 19, and symptoms of reading difficulties were observed in 78 per cent.

NEW YORK

State Medical Election—Dr. Frederic E. Sondern, New York, was chosen president-elect of the Medical Society of the State of New York at its annual meeting in Utica, May 15. Vice presidents elected are Drs. Andrew Sloan, Utica, and Leon M. Kysor, Hornell. Dr. Daniel S. Dougherty, New York, was reelected secretary. A silver loving cup was presented to Dr. Marian Craig Potter, Rochester, in recognition of her completion of fifty years in the practice of medicine.

Society News—The Schenectady County Medical Society celebrated its one hundred and twenty-fourth anniversary with an all day meeting at Ellis Hospital, Schenectady, April 12. A course of lectures on internal medicine was recently presented by the Tioga County Medical Society for its members alternately at Waverly and Owego, given by five Brooklyn physicians, as follows: Drs. George H. Roberts Jr., coronary thrombosis, Albert F. R. Andresen, biliary tract diseases, John Hamilton Crawford, cardiac failure, John B. d'Albora, ulcerative colitis, and Eugene R. Marzullo, pernicious anemia.—Dr. Clarence O. Cheney, New York, addressed the Binghamton Psychiatric Society, May 22, on "Treatment of Behavior Disorders in Children."

New York City

Joint Obstetric Meeting—The Obstetrical Society of Philadelphia, the Boston Obstetrical Society and the New York Obstetrical Society held a joint meeting in New York, April 10. Clinics were held at New York and Brooklyn hospitals and at an evening meeting at the Hotel Pennsylvania, Dr. Edward A. Schumann, Philadelphia, read a paper on "The Contribution of New York to American Obstetrics and Gynecology."

Portrait of Dr. Senior—In honor of the twenty-fifth anniversary of Dr. Harold Dickinson Senior as a member of the faculty of New York University and Bellevue Hospital Medical College, an oil portrait of him was recently unveiled in the students' lounge of the college. Dr. Senior is professor of anatomy and director of the anatomic laboratories. Dr. Benjamin Spector, professor of anatomy, Tufts Medical College, Boston, made the presentation on behalf of a committee of alumni and donors and Dr. John H. Wyckoff accepted the gift.

The Voluntary Hospital Emergency—At the annual luncheon of the United Hospital Fund for distribution of funds, May 14, a committee appointed in April to study the emergency situation of the voluntary hospitals reported that the fifty-six hospitals have a deficit of \$2,500,000 for which no provision has been made. Furthermore the hospitals have accounts, bills and notes payable for current expenses amounting to \$5,000,000, excluding capital loans. The committee recommended that before a campaign for funds is undertaken, the fund join with the municipal department of hospitals in a thorough survey of the hospital needs and problems of the city. The city, with a population of 7 million, has more than six beds per thousand of population, more than the ratio considered neces-

sary. The beds are not well distributed, however, either as to location or division between municipal and private accommodations. The committee also declared that the voluntary hospitals have not been sufficiently reimbursed for their care of city patients. Checks totaling \$450,000 were distributed to the fifty-six hospitals.

NORTH DAKOTA

State Medical Meeting in Fargo—The North Dakota State Medical Association will hold its annual session in Fargo, May 28-29, under the presidency of Dr. Jesse W. Bowen, Dickinson. According to the tentative program, guest speakers will be:

Dr. Walter L. Biering, Des Moines, Iowa, President-Elect, American Medical Association, Heart Disease.
Dr. Edward Starr Judd, Rochester, Minn., Surgical Treatment of Cancer of the Stomach.
Dr. Albert M. Snell, Rochester, Minn., Clinical Aspects of Gastric Cancer.
Dr. Ray Morton Balyeat, Oklahoma City, Allergy.
Dr. Ernest M. Hammes, St. Paul, Cerebral Hemorrhage.
Dr. Edwin F. Robb, Minneapolis, Poliomyelitis.
Dr. Wallace H. Cole, St. Paul, Arthritis.

Drs. Judd, Snell and Byrl R. Kirklin, Rochester, Minn., will conduct a gastro-intestinal clinic the first day; Drs. Robb and Cole, clinics on pediatrics and fractures, respectively, the second day. North Dakota physicians who will appear on the program include:

Dr. George C. Foster, Fargo, Bronchoscopy.
Dr. Victor J. LaRose, Bismarck, Significance of Genito-Urinary Bleeding.
Dr. John H. Moore, Grand Forks, Safer Motherhood.
Dr. Julius O. Arison, Bismarck, Cardiac Arrhythmia.

OHIO

Alpha Omega Alpha Lecture—Dr. Francis Peyton Rous of the Rockefeller Institute for Medical Research, New York, delivered the Alpha Omega Alpha Lecture at the Institute of Pathology of Cleveland, May 7, on "Studies on the Etiology of Tumors."

Society News—Drs. Charles T. Souther and Carl W. Koehler, Cincinnati, addressed the Clermont County Medical Society, Owensville, April 18, on "Anastomosis of the Large Bowel" and "Indications for X-Ray Therapy," respectively.—Dr. Robert C. Austin, Dayton, addressed the Auglaize County Medical Society on intestinal obstruction, April 12, at Lake St. Marys.

Ohio State Alumni Meeting in Cleveland—Alumni of Ohio State University College of Medicine will meet in Cleveland during the annual session of the American Medical Association at the Hollenden Hotel, Wednesday evening, June 13, at 6 o'clock. Dr. John H. J. Upham, Columbus, dean of the college of medicine, will preside, and Mr. W. N. King, Cleveland, president of the Ohio State University Alumni Association, will give an address of welcome. Mr. John Fullen, secretary of the alumni association, and Dr. Russel G. Mean, Columbus, are in charge of arrangements.

PENNSYLVANIA

Optometrist Convicted—Listed in 1932 Blue Book of Optometrists under Allentown, Pa., H. O. Ulrich, optometrist, was convicted in the Dauphin County court, March 23, of the illegal practice of medicine. Ulrich paid the costs of prosecution, repaid the victim \$45 and served thirty days in the Dauphin County prison.

Society News—Dr. Francis S. Chambers, Elizabethtown, addressed the Dauphin County Medical Society, Harrisburg, May 1, on "Principles Underlying the Prevention of Deformities in Children."—Dr. Leonard G. Rowntree, Philadelphia, addressed the Harrisburg Academy of Medicine, May 15, on recent advances in knowledge of the endocrine glands.—At the final meeting for the season of the Allegheny County Medical Society, May 15, the graduating class of the University of Pittsburgh School of Medicine and interns finishing their services in Pittsburgh hospitals were guests. Addresses were made by Dr. John W. Dixon, Wilkensburg, on "Management of Inflammation" and Gerald C. North, Ph.D., research assistant of the Wisconsin Alumni Research Foundation, Madison, on "Irradiated Vitamin D Milk."

Philadelphia

Portrait of Dr. Rugh—The senior class of Jefferson Medical College presented to the college April 26 an oil portrait of Dr. James T. Rugh, James Edwards professor of orthopedic surgery. Dr. Rugh was graduated from Jefferson forty-two years ago and has taught orthopedic surgery there for forty-one years. Dean Ross V. Patterson accepted the gift.

Seminars on Physical Therapy—The Philadelphia County Medical Society presented the sixth course of graduate seminars during the week of April 30-May 4. Lecturers were as follows:

Dr. William Schmidt: Fever Therapy
Dr. William T. Johnson: Physical Therapy in Peripheral Paralysis
Dr. John R. Moore: Physical Therapy in Orthopedics
Dr. Valentine William Murray Wright: Physical Therapy in Fractures
Dr. Josef B. Nylin: Hydrotherapy
Dr. William Bates: Influence of Posture on Disease
Dr. Frank H. Krusen: Light Therapy
Dr. Lewis C. Scheffey: Diathermy in Pelvic Inflammatory Disease
Dr. Joseph C. Doane: Histamine Iontophoresis in Treatment of Vaso spastic Conditions
Dr. Nathaniel W. Winkelman: Physical Therapy in Neurology

Society News—A symposium on rheumatic fever was presented by members of the medical department of the University of Pennsylvania before the Philadelphia County Medical Society, May 9, speakers were Drs. William D. Stroud, John C. Gittings, George M. Coates and Oliver H. Perry. Pepper—Drs. Isidor S. Ravidin and Charles C. Wolferth among others, addressed the Philadelphia Academy of Surgery, May 7, on "Immediate Results of the Treatment of the Congestive Heart by Complete Ablation of the Thyroid Gland."—Dr. Richard E. Shope of Rockefeller Institute, New York, among others, addressed the Pathological Society of Philadelphia, May 10, on "Results of the Study of Swine Influenza and Their Possible Relation to the Human Disease."

SOUTH CAROLINA

State Medical Election—Dr. Samuel E. Harmon Columbia, was named president-elect of the South Carolina Medical Association at the annual meeting in Charleston, May 1-3, and Dr. William Eggleston, Hartsville, was installed as president. Dr. Edgar A. Hines, Seneca, was reelected secretary for the twenty-fifth year. Florence was selected for the place of the 1935 meeting.

UTAH

Appendicitis Mortality Rate—The Salt Lake County Medical Society has recently launched a campaign in cooperation with the Salt Lake City Board of Health to reduce the mortality from appendicitis in Salt Lake City. In 1933 the rate was 44 per hundred thousand of population. Two questions have aroused interest: (1) Is there an unusual incidence of appendicitis in the vicinity? and (2) Do any local conditions cause delay in operation? A campaign to warn the public against taking laxatives for abdominal pain and to urge prompt medical attention has been begun. In addition, surgeons have been asked to fill out a questionnaire on all cases seen by them and incorporate it into the hospital records. It is hoped that this procedure will supply a mass of data that will permit evaluation of the factors that make for success or failure in treatment. Dr. John F. Sharp is chairman of the committee on appendicitis mortality.

VIRGINIA

Summer Courses—The University of Virginia Department of Medicine, Charlottesville, announces courses in medical sciences for the summer quarter, June 18 to July 28 intended primarily for medical students who desire to make a review. Subjects included are histology, embryology, anatomy, topographic anatomy, anatomy of the human nervous system, biochemistry, physiology, medical bacteriology, pathology, pharmacology and mental hygiene.

New Roentgen Ray Department—Fourteen rooms in the Norfolk Protestant Hospital have recently been equipped as an x-ray unit, known as the F. S. Royster Memorial, the gift of the children of Mr. Royster. A high voltage therapy unit with a capacity of 220,000 volts has been installed and there are special rooms for fluoroscopy and cystoscopy in addition to the equipment for making roentgenograms. Provision for light therapy and hydrotherapy has also been made in the new section, and electrocardiography will also be done there.

WEST VIRGINIA

Society News—Dr. James L. Blanton, Fairmont, addressed the Monongalia County Medical Society, Morgantown, April 3, on acute anterior poliomyelitis.—Drs. Hugh G. Thompson and Moritz F. Peterson discussed diabetes at a meeting of the Kanawha Medical Society, Charleston, April 10.—Dr. John H. Neff, University, Va., addressed the Ohio County Medical Society, Wheeling, April 13 on "Malignant Tumors of the Kidney." Dr. Carl H. Lenhart, Cleveland, addressed the

society, Wheeling, March 30, on pathology and therapy of peritonitis.—Dr. William Dameshek, Boston, addressed the annual meeting of the medical societies of the sixth district, Charleston, March 27, on "Primary Hypochromic Anemia."—Dr. Ray C. Otte, Wellsburg, addressed the Brooke County Medical Society, April 11, on varicose veins.—Dr. Henry Wald Bettman, Cincinnati, presented a paper on diagnosis and treatment of duodenal ulcer before the Cabell County Medical Society, Huntington, April 12.—Drs. Ralph M. Fisher and Harvey M. Andrew addressed the Lewis County Medical Society at a meeting at Weston State Hospital, March 13 on "Cardiac Physiology" and "Myocardial Degeneration" respectively.—Dr. Albert Graeme Mitchell, Cincinnati, addressed the Parkersburg Academy of Medicine, April 3, on nephritis in children.

GENERAL

A More Stringent Food and Drugs Bill—The American Society of Biological Chemists at its recent annual meeting in New York adopted a resolution favoring the passage of 'a more stringent food and drugs act, so designed as to afford ultimate protection for the consumer.'

Baltimore Wins Health Conservation Contest—Baltimore won the annual inter-chamber health conservation contest for cities of more than 500,000 population, sponsored by the U. S. Chamber of Commerce. Chicago won second place. Winners in other population classes were: Rochester, N. Y., 250,000 to 500,000; Hartford, Conn., 100,000 to 250,000; Schenectady, 50,000 to 100,000; and Hackensack, N. J., 20,000 to 50,000.

Joint Hospital Association Meetings—The hospital associations of Kentucky, Ohio and West Virginia met jointly in Cincinnati, April 17-19. A feature of the program was a public meeting on cancer at which Dr. Irvin Abell, Louisville, spoke on diagnosis and treatment of cancer and Clarence C. Little, Sc.D., managing director of the American Society for the Control of Cancer, New York, on economic aspects and progress in research.—The hospital associations of Indiana, Illinois and Wisconsin held their annual meetings jointly in Chicago, May 2-4.

Dinner of Diplomates of Special Board—The American Board of Obstetrics and Gynecology has planned a dinner and round table conference for Wednesday evening, June 13, at the Hotel Cleveland, Cleveland. Diplomates of the board and all physicians interested in the subjects are invited to be present. New diplomates granted certificates at the examination held immediately preceding the annual session of the American Medical Association will be introduced individually. Tickets may be obtained from Dr. Joseph L. Baer, 104 South Michigan Avenue, Chicago.

Association for Research in Ophthalmology—The Association for Research in Ophthalmology will hold its annual meeting in Cleveland, June 12, at the Hotel Allerton. A tentative program includes the following speakers:

Dr. Benjamin Rones: Baltimore. Genesis of Typical Coloboma.
Dr. Jonas S. Friedenwald: Baltimore. Allergic Theory of Sympathetic Ophthalmia.
Dr. Phillips Thygeson: Iowa City. Etiology of Inclusion Blepharitis.
Drs. George M. Dorrance and Paul E. Loudenslager: Philadelphia. Physiologic Considerations in Treatment of Pulsating Exophthalmos.
Dr. Ramon Castroviejo: New York. Detachment of the Retina.
Howard B. Adelman: Ph.D. New York. Embryologic Basis of Cyclopia.
George A. Bishop, Ph.D. and Howard S. Bartley, Ph.D. St. Louis. Functional Study of the Nervous Elements of the Optic Pathway.
Gordon L. Wallis: Sc.D. Iowa City. The Reptilian Retina.

Thoracic Surgeons' Meeting—The American Association for Thoracic Surgery will hold its annual meeting in Boston, May 31-June 2, with headquarters at the Copley-Plaza. Meetings will be at Harvard Medical School and clinics at the Deaconess, Peter Bent Brigham and Massachusetts General hospitals. Among speakers will be:

Mr. Arthur Tudor Edwards, London, England. Intrathoracic Malignant Disease.
Dr. Edward Archibald: Montreal. Dangers of Lobectomy in Relation to the Technique of the Operation.
Dr. Chevalier Lawrence Jackson: Philadelphia. Bronchial Carcinoma. Diagnosis by Bronchoscopic Biopsy in a Series of Fifty Cases.
Dr. Harold Jensen: Davos Platz, Switzerland. Thoracoplasty in Bilateral Cavernous Tuberculosis.
Drs. Thomas J. Kinsella and Peter M. Matliff: Oak Grove, Minn. Simultaneous Bilateral Artificial Pneumothorax in Treatment of Pulmonary Tuberculosis.

Association for Study of Goiter—The annual meeting of the American Association for the Study of Goiter will be held in Cleveland, June 7-9, with headquarters at the Wade Park Manor. At the first session a symposium on hyperthy-

roidism will be presented by Drs. Stuart D. Gordon, Toronto, Urban Maes, New Orleans, Howard M. Clute, Boston, and Edward H. Rynearson, Rochester, Minn. Dr. George W. Crile, Cleveland, will give an address at the annual banquet on "Comparative Studies of the Thyroid Gland in Animals." Among other speakers will be

Dr. Hermann L. Blumgart, Boston, Indications, Contraindications and End Results in Treating Various Forms of Cardiovascular Disease by Complete Removal of the Thyroid

Dr. Arnold S. Jackson, Madison, Wis., A Survey of Cretinism in the United States

Dr. William F. Rienhoff, Jr., Baltimore, Histologic Structure of the Thyroid in Patients Cured of Hyperthyroidism by Operation

Dr. Louis J. Karnosh, Cleveland, Psychoses in Hypothyroidism and Hyperthyroidism

Medical Bills in Congress — Changes in Status The Senate, May 16, by a vote of 26 to 22, agreed to take up for consideration S. 2800, the Copeland food, drugs and cosmetics bill. H. R. 3768 has been favorably reported to the Senate, proposing to change the name of the retail liquor dealers' stamp tax in the case of retail drug stores or pharmacies to "medicinal spirits stamp tax." **Bills Introduced** S. 3630 introduced by Senator Wagner, New York, proposes to provide compensation for disability or death resulting from injury to employees in interstate commerce. The bill would apparently authorize an employer to select the physician to treat an injured employee. H. R. 9616 introduced by Representative Woodruff, Michigan, would authorize the withdrawal of alcohol tax free "for the use of any clinic operated for charity and not for profit including use in the compounding of bona fide medicines for treatment outside of such clinics of patients thereof but not for sale."

A Million for Infantile Paralysis Fund — A sum of \$1,003,030.08, to be used for the benefit of Georgia Warm Springs Foundation, Warm Springs, Ga., was presented to President Roosevelt, May 9, in a ceremony in the White House. Of the total, \$100,000 will be used "to stimulate and further the meritorious work being done in the field of infantile paralysis" outside Warm Springs, "so that the greatest encouragement may be given to others interested in this problem." In addition, \$650,000 will be set aside for "the furtherance of the present work done at Georgia Warm Springs Foundation," of which President Roosevelt is the head and founder, while the balance of \$253,030.08 will be used "for building maintenance, and contingencies of the foundation." Executed on parchment, three feet long and eighteen inches wide, the check was presented to President Roosevelt by Rear Admiral Cary T. Grayson. The fund represents the public contributions made at the recent charity balls held in honor of President Roosevelt's fifty-second birthday. The foundation has been in operation since 1927, when it was incorporated not for profit. Only the cost of maintenance and treatment is charged. A patients' aid fund enables the management to admit a few cases at a reduced rate, the amount of reduction depending on the financial circumstances and probability of marked improvement. Preference is given to adults who need treatment in order to increase their ability to become self supporting.

PUERTO RICO

Medical Association Officers — At the annual meeting of the Medical Association of Puerto Rico in December 1933 Dr. Pablo Morales Otero, San Juan, was elected president and Dr. Julio R. Rolenson Santurce, secretary. The next session will be held in San Juan in December.

Government Services

Venereal Disease Information

The U. S. Public Health Service wishes to call the attention of physicians to the monthly abstract journal *Venereal Disease Information*, published by the service for the past ten years for the information of physicians, health officers and others. It contains usually one original article and abstracts of current literature pertaining to these diseases. More than 350 medical journals are reviewed for the abstracts. The journal may be ordered from the Superintendent of Documents, Government Printing Office, Washington, D. C., at 50 cents a year. The announcement points out that this nominal charge represents only a part of the expense of preparing the journal, which is a contribution of the public health service in its program directed against the venereal diseases.

(From Our Regular Correspondent)

April 28, 1934

The Reform of Medical Education

The reform of medical education has been under discussion for the last few years. Medical teachers, physicians and students agree that the curriculum is overloaded. The British Medical Association appointed a committee on medical education, which has now presented a lengthy report advocating drastic reforms. The primary object of the medical curriculum is described as the production of a practitioner with the right attitude toward professional duties, ability to deal in the early days of practice with such conditions as may confront him, and such basic knowledge and mental training as will enable him to profit by experience. At the same time there should be such a coordinated course of study as will make the student an educated person and not merely a skilled technician. Throughout the curriculum, attention should be directed primarily to health and its preservation, perfection or restoration, and not to disease. The student should start the curriculum with adequate previous equipment. The curriculum should not be regarded as divided into separate blocks of study, but all subjects should be to some extent interdependent. The preliminary sciences in relation to the rest of the medical course, and also anatomy and physiology in relation to clinical study, should be continuous in their application, revision and development. There is no need to prescribe any strict uniformity of method in the application of the curriculum or in the system of teaching adopted. Indeed, it is desirable to encourage a wide liberty of choice in the different schools, provided certain broad requirements are satisfied.

Before registration, the student should be required to show a somewhat higher degree of general education than the minimum now required, and also a sufficient knowledge of physics, chemistry and the general principles of biology. His general education should include the English language and literature, a foreign language and perhaps history. The usual duration of such a course should be two academic years, within which, with average ability, he should get a thorough grounding in physics, chemistry and biology, while continuing his general education. Representatives of the teaching profession consulted by the committee unanimously held that registration of a medical student below the age of 18 years should not be allowed.

ANATOMY AND PHYSIOLOGY

Anatomy and physiology should be taken as interrelated subjects with reference to their subsequent clinical application and should be pursued largely in relation to the living body. During the course the student should become familiar with the methods of manual examination and be taught the use of the clinical thermometer, ophthalmoscope, laryngoscope, rhinoscope, otoscope, estimation of blood pressure, examination of the blood and analysis of secretions. Anatomy should be intimately concerned not merely with structure but with the relation of structure to function and with occasional reference to cases of impaired function as manifested clinically. At present too great demands are made on the student's time in the course on anatomy and physiology. Dissection of every part of the body is unnecessary. Dissections prepared by experts are of great value. Meticulous detail, such as the exact bony attachments of muscles and the relations of the less important arteries, veins and nerves should not be required. Similarly, as regards physiology a good deal of time might be saved by releasing the student from preparing all his own histologic sections and preparing and carrying out many laboratory experiments. On

the other hand, greater attention should be given to genetics, growth and mental function, instruction in which has usually been inadequate. The first is almost a new science since the last revision of the curriculum.

MEDICINE

Of the teaching of medicine in the schools the committee does find grounds for serious criticism. But there appears to be need for more abundant opportunity for the student to have experience with those minor operative procedures regarded within the province of the general practitioner, such as the taking of blood specimens, intravenous medication, lumbar puncture and diagnostic exploration of serous cavities. It would be of great advantage if the student received as a matter of course some of the instruction given to nurses. This might be given by members of the nursing staff. How can the physician supervise the methods of nurses without practical knowledge of these? He should have full opportunities of acquiring skill in special methods of examination, such as of the fundus of the eye, the vocal cords and the ear. He should receive greater instruction in the psychonuroses. Though these will be always with him in his daily practice as a physician, they now receive less attention than the much rarer psychoses.

SURGERY

Much criticism has been directed to the teaching of surgery. The student should become familiar with the diagnosis and treatment of all the common surgical diseases and injuries and have opportunities of gaining skill in the treatment of fractures and dislocations and the performance of minor operations. An acquaintance with the more common major operations is important, but the mere watching of operations in the theater is largely a waste of time. The treatment of septic conditions in their earliest stage is an essential function of the general practitioner. Therefore every student should have the experience of dealing surgically with such conditions as whitlow, carbuncle and cellulitis. Knowledge so acquired can be applied in many other surgical directions.

APPRENTICESHIP BEFORE INDIVIDUAL PRACTICE

In former times a student was trained by apprenticeship to a practitioner. Now the training required for license to practice is entirely hospital. The most revolutionary proposal of the committee is the revival of the apprenticeship after the passing of the final examination. This examination cannot be taken before the close of the fifth year of the curriculum. On passing it a full license to practice independently will not be granted. This can be obtained only after a further period of clinical experience under supervision that would normally extend to nine months and never be less than six. This period might be occupied (1) in a resident appointment in a teaching or other hospital, (2) as a clinical assistant in an approved hospital or clinic, (3) as pupil assistant to an approved general practitioner or (4) in regular attendance at hospital practice in a medical school.

Improved Medical Services for South African Natives

Mr Hofmeyr, minister of health in South Africa, made an important statement in the house of assembly on the government's intention to improve medical services for the natives. It has long been recognized that medical services in the native territories are pitifully inadequate. In some areas there is only one physician to 30,000 people. It is impossible to supply an adequate number of fully trained native physicians but the government intends to train several hundred native aids. These will be given three years of professional training and will work on a system similar to that in Tanganyika and Uganda under the supervision of district surgeons. The training will be at a native college financed largely by \$375,000 given by the chamber of mines in recognition of services ren-

dered by the native peoples in the gold mining industry." The government will assist additionally in the training overseas of a selected number of native physicians. It also will appoint a commission to investigate the position of the Cape colored population. These people, who are a mixture of Hottentots, slaves from the East Indies, Bantu and Europeans, are now a more or less well defined racial entity, and investigation of their special problems is long overdue. The government also intends to expand the antituberculosis measures by the institution of clinics and hospitals in all the provinces for colored patients.

Diseases Transmitted by Blood Transfusion

The Societe des medecins des hopitaux de Paris devoted recently a long session to discussing diseases transmitted by blood transfusion. Since the creation at Paris of special centers with professional donors, the number of blood transfusions has increased. In connection with the official services of the Assistance publique, a philanthropic society has been founded, which is developing an ever increasing activity. At its recent session it was reported that 220 transfusions were provided in 1929. The number was increased to 3,738 in 1932 and to 5,272 in 1933. At the meeting of the Societe des medecins des hopitaux, special attention was paid to the accidents that occur as a result of transfusions, especially the transmission of syphilis, malaria and infectious diseases. Carnot, Caroli and Maisson reported a case of syphilis transmitted by a donor to a typhoid patient affected with profuse and grave intestinal hemorrhages. The first two transfusions had been made with the aid of a professional donor but the third was an emergency transfusion made with the aid of a hospital patient who appeared healthy and on whom there was no time to do the Wassermann test, which later was found positive. The patient recovered from the typhoid but presented, eighty days later, a typical roseola, which began with a slight eruption at the site of the puncture. Carnot stated that only twenty such cases have been recorded in France and about a dozen in America. They are almost unheard of in well organized transfusion centers. Tertiary syphilis does not appear usually to give rise to accidents after transfusion. A donor affected with eye symptoms and presenting a positive transitory Wassermann reaction was used for eight transfusions without transmitting syphilis. Nevertheless, Spillmann observed a retrograde and syphilitic infection in a physician infected by a patient who presented syphilis of six years' standing. The authors conclude that it is advisable to select donors from among professional donors and to repeat frequently the Wassermann test. Mr Tzanck reported the case of a donor with a negative Wassermann test who presented later eye lesions that evidenced tertiary syphilis. This donor furnished his blood eighteen times without untoward incidents. In the colonies, in which white persons are commonly affected with grave malarial anemia, the only donors safe to use are Negroes. Unfortunately, most of the Negroes are syphilitic. Tertiary syphilis with a negative serologic test never causes untoward incidents. The case of a physician was recalled who, having served as a donor to a patient who presented a grave hemorrhage after confinement, revealed a roseola in his own person twenty-four days later. This unusual infection was probably due to an error in the technic which permitted a reflux of blood from the recipient to the donor. Inquiry revealed that the patient showed evidence of syphilis, her husband presented a positive serologic test. Mr Gougerot cited a case of syphilis transmitted by a donor in whom the Wassermann test was negative but in whom a chancre developed a few days later.

Mr Gougerot and Mr Dufour observed a veritable epidemic of syphilis among the clientele of a physician who gave alleged rejuvenating treatments by the injection of blood serum of young persons and who was content, in order to avoid the necessity of the Wassermann test, to add mercuric cyanide to the blood serum thus injected. The mercuric cyanide had no effect on the spirochetes. To the suggestion of Mr Milian, who proposed the use of animal blood to avoid all these risks, Tzanck replied that such use is dangerous and that fatalities may result if doses slightly in excess of normal are employed. Numerous speakers cited cases of transmission of malaria through blood transfusion. With respect to malaria, Mr Pinard pointed out that one may observe an ordinary infection if it is a question of a first attack or of manifestations of superinfection, with abortive reactions, in persons who have previously presented malarial attacks. The addition of mercuric cyanide to malarial blood does not prevent malarial attacks from developing. Mr Harvier reported the case of a malarial attack following transfusion for hematemesis. The donor, in apparently good health, had never had a malarial attack (he had been taking quinine as a preventive measure), but he had resided in the colonies. Examination of a thick smear revealed the presence of parasites.

The author recalled that many persons who have resided in the colonies have late attacks of malaria, hence a malarial person who has not had an attack for eighteen months would not be regarded as cured. Such flareups are well known, for even though the hematozoon may have disappeared from the peripheral blood it may persist in the deep lying organs for years, the malaria reappearing in connection with a traumatism, a chill, and the like. He therefore recommended the rejection of all prospective donors who have resided in the colonies, even though the Henry reaction is found to be negative. P. E. Weil confirmed the existence of latent malaria in association with splenomegaly. Tzanck and Juliet reported four cases of septicemia as transmitted from the recipient to the donor by reflux of blood, which always evidences some grave technical error, even though citrated blood is employed.

Mr Laubry exhibited an apparatus devised by Henry and Jouvet, which is designed to prevent such accidents.

Lyons Invaded by Mosquitoes

Lyons situated at the confluence of the Rhone and the Saone, has many rainy days, and mosquitoes constitute a plague in that region. Fortunately, the mosquitoes are not *Anopheles* and are not hosts of malaria, at least at present. But their continual attacks, during a large part of the year, make life almost unbearable. The magnificent Hospital de Grange Blanche (just recently completed with the aid of funds furnished by the Rockefeller Foundation), which represents the highest development in hospital construction, is so infested by mosquitoes that the patients constantly complain. The city of Lyons includes in its annual budget 20,000 francs (\$1,200) to carry on an everlasting crusade against the mosquitoes. Dr Nove Josserand and Mr Sahuc presented recently to the municipal council the results of their studies on this subject. They concluded that these mosquitoes (*Culex pipiens*) are not brought in by the winds but are hatched in the buildings of the city, in the eaves under the roofs, and especially in the cesspools, to which protruding tile pipes establish communication with the outer air and through which the female mosquito descends to deposit its eggs on the excrementa. They belong, therefore, to the category that Dr Legendre has termed "Stercoraires." The only remedy, according to Nove-Josserand, would be to pour a light oil into the toilets. Dr Garin, on the contrary, regards such a measure as merely palliative. In his opinion the mosquitoes will not be eliminated from Lyons until a complete sewer system has been installed in the city.

Divorces in the German Reich, 1919-1932

According to statistics compiled by the Reichsgesundheitsamt, there were more than 16,000 divorces in 1913 among the 11 million married persons, or 152 per 10,000. In the fourteen postwar years 1919-1932 the percentage of divorces just about doubled. In the years 1920-1922, in which a large portion of the war marriages were dissolved, the figure rose to 30 per 10,000. During the period 1923-1932 the percentage of divorces did not recede to the prewar condition but ranged around 86 per cent higher, or 282 per 10,000. In 1932, the last year for which statistics are available, 42,000 of the 14 million married persons were divorced by court action, or 297 per 10,000. The slight fluctuations in most of these years leads to the conclusion that the frequency of divorce is not controlled so much by changing economic conditions, and that the fairly uniform postwar figures may be regarded as an expression of a decline of family unity and solidarity. Before the war, the alleged grounds for divorce in 48 per cent of the trials were adultery, bigamy and various forms of unchastity, 40.8 per cent of violations of conjugal duties and dishonorable behavior, and 9 per cent of wilful desertion. Only 2.2 per cent of the cases were based on mental illness and the like. The first postwar years (1919-1921) brought considerable increase in the number of divorces due to adultery, bigamy and the like, the proportion reaching 64.3 per cent, whereas divorces due to violations of conjugal duties or dishonorable behavior declined to 31.6 per cent, the divorces due to wilful desertion dropped to 2.9 per cent. During the following years the importance of adultery as a ground for divorce declined, and violations of conjugal duties, together with dishonorable behavior, increased, the figure reaching 63.2 per cent in 1932, whereas adultery was the charge in only 33.4 per cent of the cases.

The greatest divorce frequency was for marriages contracted from three to six years previously (30.5 per cent of all divorces). A comparatively large number of divorces concerned marriages of long duration. It was estimated that nearly one fifth of all legal decisions had to do with marriages that had continued fifteen years or more.

Observations on the Results of Castration

In connection with recent German legislation, Professor Lange, psychiatrist, of Breslau, reports on experiences to date with castration. Reports of observations on castration and its results are fairly numerous, although not systematically arranged as yet. The best known are those on church choir singers among certain religious sects. In recent years, Denmark and some cantons of Switzerland have adopted legislation similar to that of Germany. The reason why the results in those countries have been particularly good is that operations have been performed only at the request of the person intimately concerned, the request itself furnishing evidence of a desire to reform.

Lange's observations are based mainly on a study of the official reports on soldiers wounded and operated on during the war. A follow up of these patients supplies a more objective basis than the subjective accounts, which are often veiled or exaggerated. The results of later examinations are recorded in the army reports. In most cases, in addition to the first examination previous to discharge from the service, there was a second examination in 1919 and a further control examination during the period 1920-1922. Among 330 patients, the later life experiences of 250 were recorded. The age of the patient at the time of castration was below 25 in more than 300 instances. Some patients had undergone complete castration.

some had been affected with bilateral tuberculosis of the testes, and still others presented small testicular remnants. Potency was seldom destroyed, and in some instances there seems to have been even an abnormal sexual desire often with a discrepancy between potency and libido, or even inversion of the sex impulse. Of the patients undergoing complete castration, ninety married. During the first years after marriage there was no reduction of energy, working capacity or the like in some instances even an increase in artistic trends was observed. There was no increase in the incidence of suicide and no evidence of early mortality. In some patients vasomotor disturbances developed, while in others neurasthenia and depression states appeared. As time went on there were changes in body form and hair growth, height and weight, evidences of physical and psychic effeminacy, and less frequently premature senility along with climacteric disturbances. These appeared usually soon after age 40.

All such emotional fluctuations would doubtless be more marked in persons with mental disease. An individual prognosis is impossible. Lange suggested the creation of a center for the systematic elaboration of the results to be secured. The observations to date may be regarded as a support for the recent legislation. The fact must never be forgotten, however, that castration is a serious intervention that is often associated with grave damage to both body and mind.

Photography of Beginning Cataract

With the cooperation of the Firma Zeiss, the director of the ophthalmologic department of the Allerheiligen-Hospital in Breslau has constructed an apparatus with which changes that occur in the crystalline lens during the development of cataract can be recorded by means of photographs. The slit lamp method is not adapted to this purpose, but the speculum termed the lupenspiegel furnishes pictures giving a good general survey of the field. The photographic method is complicated. Beginning with a mild light one must suddenly go over to the strongest light in making the photograph. The photograph is taken with a camera which has an arrangement that enables the operator to change the intensity of the illumination and to insert the photographic plate at the same moment. The camera can be set to photograph the same sites again in precisely the same manner, which makes possible a continuous control by means of projections made several weeks or months apart. At first only the sites with the most marked changes are photographed, three projections are sufficient to bring out plainly the relations of the deeper tissues. The changes that the eye undergoes are of an exceedingly manifold type.

Changes in Hemoglobin in Relation to Porphyrinuria

Research on the porphyrins has been carried out chiefly by H. Fischer of Munich and his collaborators. The importance of the porphyrins extends far beyond the known disease groups. On the basis of recent research, particularly that of Schreus, the Dusseldorf professor of dermatology and that of his collaborator Carrie there is a close connection between changes in the hemoglobin and porphyrin excretion. For the body, porphyrins in quantities that only slightly exceed the physiologic norm exert an important influence although their actions have not as yet been carefully studied. The symptoms affecting the intestinal tract, the kidney (oliguria), the nerves and the blood vessels in lead porphyrinuria, and in other diseases associated with disintegration of the blood are in all probability due to the effects of porphyrin and hence can be grouped together as porphyrinopathies. Research on these syndromes is the task of the clinic. Furthermore important disclosures concerning the closer connection between blood disintegration and porphyrin excretion are anticipated. It has been found that even small doses of arsenic produce blood disintegration

and porphyrin excretion, from which fact it may be concluded that the therapeutic effect of the administration of arsenic is due to the blood disintegration it causes.

ITALY

March 15, 1934

Vaccine Treatment of Undulant Fever

At a recent session of the Società medico chirurgica of Catania, vaccinotherapy by the intravenous route in undulant fever was discussed by Dr. Guglielmo, who based his statements on an experience with more than 130 cases, with 100 per cent of recoveries. The treatment was harmless at all ages (from 4 to 77) and in all conditions, even the most grave, not excepting renal involvement. The majority of cases require about a month's treatment, with massive doses of vaccine containing 75 million germs. There is a possibility of short courses of treatment (two injections, or sometimes a single injection, with from 5 to 10 million germs) and also the possibility of prolonged treatment (a month and a half, with from twelve to fourteen injections, massive doses up to 125 million germs). Fichera obtained good results in the nine cases in which he tried the method. Grasso also had treated ambulatorially twenty cases by this method, obtaining sixteen recoveries and four notable improvements, still under treatment.

Signorelli considered the various types of reaction observed. In persons not affected with undulant fever, fever is not ordinarily produced as the result of intravenous injections of small doses of vaccine. But in some cases the reaction does occur, and hence an absolute diagnostic value cannot be given to this test in doubtful cases of undulant fever. Furthermore, with small doses of vaccine a frank febrile reaction may not occur even in true undulant fever patients.

Cordaro studied in twenty-eight cases the sedimentation speed of the red corpuscles. The febrile reaction that follows vaccinotherapy is accompanied by a considerable increase of the sedimentation speed, which however, after the reaction has ceased, returns to the original values. When defervescence has been brought about, the sedimentation speed decreases slowly and reaches almost normal values in about ten days.

Sorge called attention to the practical value of Burnet's skin reaction for the diagnosis of undulant fever.

Early Aid for Tuberculous Patients

At the suggestion of the Sanità pubblica, the commission appointed to study the diagnosis and early aid of tuberculous patients held a meeting presided over by Professor Micheli. The commission pointed out that it is desirable to extend gradually compulsory insurance against tuberculosis, applying it more generally to persons employed to render personal service, carriers and persons engaged in the handling of food products. Every effort must be made to bring it about that persons with tuberculosis shall be treated early. To that end the provincial antituberculosis societies should be financed more generously and should be organized in such a manner as to be able to function as general consultation centers and attract thus a greater number of suspected patients.

Method of Exploring the Functioning of the Liver

Before the Accademia delle scienze medico chirurgiche of Naples, Dr. Zappacosta recently described a method for the determination of glycocholic acid in the blood. He injected glycocholic acid by the intravenous route in the amount of 3 or 4 mg per kilogram of body weight, and a quarter of an hour after the injection he no longer found it in the blood of forty-five normal individuals. On the other hand, in forty-six patients with various disturbances of the liver he observed that the

glycocyamine is still present in the blood after the same period of time and even in a conspicuous quantity—in the majority of the cases proportionately to the decreased functional capacity of the liver. In these liver patients the author employed as controls also other means of exploration, including provoked bilirubinemia and the amino-acidemia curve. Dr Zappacosta concludes that the test is highly sensitive.

The Death of Professor Angelucci

Dr Arnaldo Angelucci, professor emeritus of clinical ophthalmology at the University of Naples, died recently. He had a brilliant career. At the age of 31 he became director of the Clinica di Cagliari, from which he passed to that of the universities of Messina and Palermo and finally to the University of Naples, where he was for twenty-five years.

His most notable studies are those on the function of the retina, in which he explained the complex changes that take place in the retina through the effects of light. He found that such changes are observed also in the parts of the central nervous system that have direct relation with vision, whereupon he formed a new theory of vision. He studied also the physiopathology of the cervical sympathetic in its relations to the eye, the loss of secretion of the aqueous humor, and the nutrition of the eye. Owing to these studies, he was entrusted with writing the chapter on the physiology of the eye in the *Enciclopedia francese di oftalmologia*.

He interpreted glaucoma as due to a vascular change. This conception he confirmed later—also with reference to infantile glaucoma. Professor Angelucci was the first to discover in patients with spring conjunctivitis a syndrome characterized by an excitable temperament, palpitation and vasomotor disturbances, which he termed the Angelucci syndrome and which today is interpreted as an expression of neuro-endocrine disturbances associated with the still unknown cause of the disease.

Angelucci devised operative procedures for the treatment of senile ectropion of the lower eyelid and of paralytic ptosis of the upper eyelid. He was a pioneer in studies on constitution in ophthalmology. To trachoma Angelucci had devoted himself in recent years. With regard to treatment, he emphasized the advantages of autoserotherapy and for prophylaxis, the need of improving the general condition of children with adenoids.

He established in his Clinica di Napoli a combination school and sanatorium for trachomatous children of the elementary classes, and a combination institute and preventorium for the treatment of constitutional diseases in school children. He founded in 1893 the *Archivio d'oftalmologia*, a journal that is still flourishing.

Council on Research

The Consiglio nazionale delle ricerche met in Rome, March 8. The head of the government was present. Senator Marconi, president of the council, gave an account of its activities during the year. Research was conducted on a possible submicroscopic type of malarial parasite. The first results showed that there are differences between the action of strains artificially transmitted from man to man for therapeutic purposes and the genuine parasitic strains. Questions pertaining to alimentations continue to be the subject of intensive studies. Twelve university laboratories have about completed their research on the nutritional value of food products of Italian origin. An inquiry into the alimentations of the various classes of the Italian people is being conducted, and a study is being made on the population of the swamps recently drained. With the latter research is associated an investigation on the somatic and demographic characters of the families that have settled here, in order to ascertain their adaptation to the new surroundings. Research is also being carried on to discover the causes for the depopulation of the mountain regions.

JAPAN

(From Our Regular Correspondent)

March 31, 1934

Official Japanese Physicians in Manchuria

A number of Japanese physicians have been appointed official practitioners in the new empire of Manchokuo. They established in the remote parts of the country, where no properly qualified doctors practiced. Here only the old Chinese medicine was represented and a kind of medicine men practice in the most primitive manner. Now the official physicians have been placed in every prefecture. Their duties are to prevent epidemics, to do research on local diseases, to vaccinate, to take charge of school hygiene, to hold inquests and necropsies, to give free medical treatment to the poor, and to gather medical statistics. In time of emergency they must be at the scene to render medical aid on the spot. For those duties and work they are paid reasonably well and are furnished with offices, general medical equipments and dwelling houses. They can, of course, do private practice also but they and their families cannot set themselves up in the drug or chemical business.

Industrial Guild Hospitals

According to the annual report of the central industrial guild, sixteen hospitals belong to the guild, there are sixty-five consulting offices, each of which is attached to one sickness union. As for the maintenance of the hospitals and offices, nearly half of them are said to face economic difficulty. A union that has 2,000 members or so in the same district is successful, but the union with 400 or 500 members is a failure because it is in remote villages or small towns, where the patients can hardly pay in cash owing to the depression. When the patient leaves a medical fee unpaid, he prefers to go to another practitioner who is rich enough to wait until the end of the year to be paid. The union established by the lower classes cannot do this.

The International Culture Association

The Kogakukai, under the charge of Dr. Choei Ishibashi, has recently changed its name to the International Culture Association, which aims to promote international understanding through learning foreign languages, especially through medical science. The society has long been making great efforts to introduce German among physicians as a convenience for them in studying medical science. They intend to extend the work to French and English. The association endeavors to assist physicians with foreign languages by translations and by introducing foreign medical science in this country, and vice versa.

The Question of Reporting All Tuberculous Cases

In the revision of the regulations for the prevention of tuberculosis, there are these important facts. The government insists on the need of reporting every case of tuberculosis to the police, without which, it is asserted, no prevention can be expected. On the contrary, the antagonists, chiefly found among practitioners, indicate that compulsory notification will seriously affect a patient's social relations such as unemployment and marriage. Who will be honest and courageous enough to consult a physician at the peril of those disadvantages in social affairs? He would rather be a good customer of the druggist than of the practitioner. This would tend not only to spread the disease more and more but tempt physicians to conceal the cases of tuberculosis from government officials. Under present conditions they could not accommodate all the tuberculous patients if reported, owing to the great shortage of hospital beds for such cases. Moreover, it should not be forgotten that physicians will be hard hit by this system. The establishment of dispensaries was debated at length in a meeting of the national health investigation committee last winter, and it was

concluded that one dispensary ought to be established for each hundred deaths from tuberculosis, there is one dispensary to each 100,000 of population at present. As to the function of the dispensary, there is a controversy: physicians want the dispensary to be only a consultation office which would not undertake treatment; the government's idea is that the dispensary should give not only advice but medical treatment, if necessary. With debates to everybody's satisfaction, the policy is expected to be agreed on before long.

The Loss Charged to Tuberculosis

Dr E. Kanasugi, veteran physician, and member of the house of peers, made a speech in the present session on fixing the national policy of stamping out tuberculosis in Japan. He presented as the basis of his argument the following facts: The deaths in 1931 from this disease numbered 121,874, that is 18.64 for 10,000 of population, 76,750 of the deceased were between 15 and 34 years old. Moreover, this number may be far smaller than the true number. The economic loss may be roughly estimated at over 400,000,000 yen if each case is allowed one yen a day for medical treatment. The loss of the families may be estimated at millions of yen besides the loss to industry, education, and the army. The comparison of these deaths with the hospital beds in 1931 shows only 7.5 beds for tuberculosis per hundred deaths while England has 64.7 beds, America 112.28 beds, and Germany 115.5 beds. In England there is one dispensary for every 50,000 of population, in America one for 28,000 and in Germany one for 47,000, while in Japan there are only a few dispensaries in the greater cities as if they were established only as samples. The sum of 3,500,000 yen, including the national and local governmental expenditure and that of various nonofficial societies, is paid every year for preventive work, that is, only 5.3 sen (or about 2 cents) a man, while England spends 2 shillings a man and Germany 2 marks.

In the diet, the prime minister declared that the government would lose no time in adopting a better national policy against tuberculosis. The only question is how to raise the large sum necessary. Plans are said to be under consideration by the authorities, such as an increase of the tax on some luxuries.

Another Study on Menstruation

The *Women's Review* or *Fujin Koron*, a monthly magazine for women, after six months of hard work under the guidance of prominent physicians has issued a pamphlet called "menstruation reports," which is based on replies from over 6,000 women. The reports were given voluntarily and have come from almost every class and district of the country, including both the married and the unmarried. According to this report the first menstruation of these Japanese women occurred at the average age of 14 years and 3 months. Out of 4,884 women, 1,435 had the first flow in winter, 1,315 in summer, 1,184 in spring and 950 in autumn. The average menstrual cycle is thirty-one days, but the normal lies anywhere between twenty-seven and thirty-four days. Among 1,612 women the period lasted five days, 1,160 women, four days, 1,071 women, six days, 481 women, seven days and 363 women, three days. Among 3,074 women, 2,559, or 83.25 per cent, did not feel pain at menstruation, while 515, or 16.75 per cent, did feel pain.

A Daily Medical Paper

Dr S. Tsuchiya, a member of parliament who is proprietor of the *Japan Medical World* a weekly journal has announced that he and his colleagues would publish a daily medical paper. This is the first attempt in this country to have a daily medical paper and 50,000 physicians throughout the country are glad it is reported to have a powerful protector of their own kind in such troubled times. The new medical paper is going to fight for the doctors.

Marriages

WILLIAM JENNINGS SWEENEY, Vermilion, S. D., to Miss Edith Keeling Maggart of Winnetka, Ill., May 5.

EUCLID MONROE SMITH, Hot Springs National Park, Ark., to Miss Madge Eloise Wootton, February 20.

JOHN WHITTIER LEECH, West View, Pa., to Miss Katherine Enid Evans of Pittsburgh, May 12.

HOWARD CHANDLER SMITH to Miss Mary Burnam, both of Baltimore, April 26.

LEONE M. SCRUBY, Des Moines, Iowa, to Mr. Oscar Lofquist, February 15.

Deaths

Clement Cleveland, New York, College of Physicians and Surgeons in the City of New York, Medical Department of Columbia College, 1871, fellow of the American College of Surgeons, past president of the American Gynecological Association and the New York Obstetrical Society, at one time vice president of the American Society for the Control of Cancer, surgical director emeritus to the Woman's Hospital for many years on the staff of the Memorial Hospital and formerly on the staff of the City Hospital, aged 90, died, April 16, in Palm Beach, Fla.

Bern Budd Gallaudet, New York, College of Physicians and Surgeons in the City of New York, medical department of Columbia College, 1884, member of the Medical Society of the State of New York and the American Association of Anatomists, associate professor of anatomy at his alma mater, consulting surgeon to the Bellevue Hospital, aged 74, died March 30, of intestinal obstruction due to chronic diverticulitis.

Melvin J. Locke, Bellefonte, Pa., Hahnemann Medical College and Hospital of Philadelphia, 1891, member of the Medical Society of the State of Pennsylvania, formerly secretary of the Center County Medical Society, fellow of the American College of Surgeons, on the staff of the Center County Hospital, president of the school board, aged 66, died, April 14, of septic meningitis.

William Walter Beattie, Montreal, Que., Canada, McGill University Faculty of Medicine, 1920, lecturer in bacteriology at his alma mater, member of the Society of American Bacteriologists, formerly assistant on the staff of the Rockefeller Institute for Medical Research, aged 39, was instantly killed in an automobile accident, April 13, near Biggleswade, Bedfordshire, England.

Jocelyn Joseph Emmens, Medford, Ore., Medico-Chirurgical College of Philadelphia, 1905, member of the Pacific Coast Ophthalmological Society, on the staffs of the Community Hospital and the Sacred Heart Hospital, aged 53, died April 13, in the Scripps Memorial Hospital, La Jolla, Calif. of cerebral hemorrhage.

Edwin Fred Gissler Jr., Brooklyn, Eclectic Medical College of the City of New York, 1897, member of the Medical Society of the State of New York, aged 58, on the medical board of the Evangelical Deaconess Hospital, where he died, April 24, of atrophic cirrhosis of the liver, and arteriosclerotic heart disease.

Francis Marion Thigpen, Montgomery, Ala., Tulane University of Louisiana Medical Department, New Orleans 1891, member of the American Laryngological, Rhinological and Otological Society, on the staff of St. Margaret's Hospital, aged 66, died, April 22, of influenza and cardiorenal complications.

Albert S. Rudy, Lima, Ohio, Medical College of Ohio, Cincinnati 1884, member of the Ohio State Medical Association, at one time city health officer and member of the board of education, formerly on the staffs of the Lima City and St. Rita's hospitals, aged 78, died, April 6, of carcinoma of the liver.

Charles Oren Burke, Atlanta, Ill., Jefferson Medical College of Philadelphia 1887, member of the Illinois State Medical Society, served during the World War, formerly on the staff of St. Joseph's Hospital, Bloomington, aged 69, died, May 3, of chronic myocarditis, hypertension and arteriosclerosis.

John William Gunn, Boise, Idaho, Cooper Medical College, San Francisco, 1884, past president of the Medical Association of Montana, past president and secretary of the Silver

Bow (Mont) County Medical Society, formerly health officer of Butte, aged 78, died, April 8, in San Francisco

Allen Joseph Ingersoll, Mentor, Ohio, Western Reserve University Medical Department, Cleveland, 1893, member of the Ohio State Medical Association, for thirty-three years a member of the school board, aged 72, died, April 11, of injuries received when he was struck by an automobile

Ross Grosshart, Tulsa, Okla., Kansas City (Mo.) Medical College, 1899, member of the Oklahoma State Medical Association, past president of the Tulsa County Medical Society, on the staffs of the Morningside and St. John's hospitals, aged 56, died, April 15, of coronary occlusion

John Dougherty Joseph Curran, Atlantic City, N. J., Georgetown University School of Medicine, Washington, D. C., 1903, served during the World War formerly instructor in pediatrics, Jefferson Medical College of Philadelphia, aged 56, died, April 18, of cardiorenal disease

Clarence John Burns, Columbus, Ohio, Ohio State University College of Medicine, Columbus 1919, on the staff of the Mount Carmel Hospital, aged 38, died, March 17, in Tucson, Ariz., of lung abscess, bronchiectasis and cardiac decompensation

Adelbert Morton Austin, Quincy, Ill., Washington University School of Medicine, St. Louis, 1904, past president of the Adams County Medical Society, on the staff of the Blessing Hospital, aged 53, died, March 20, at his home in Mendon, of heart block

Daniel Webster O'Connell, New Britain, Conn., College of Physicians and Surgeons, Baltimore, 1905, member of the Connecticut State Medical Society, on the staff of the New Britain General Hospital, aged 53, died, March 18, of coronary occlusion

John Richard Taylor, Madison, Wis., College of Physicians and Surgeons of Chicago, School of Medicine of the University of Illinois 1899, served during the World War aged 72, died suddenly April 5, in London, England, of heart disease

Max Reynolds Gabrio, Philadelphia, Jefferson Medical College of Philadelphia, 1913, instructor in ophthalmology, University of Pennsylvania School of Medicine on the staff of the Wills Hospital, aged 49, died, April 26, of heart disease

Robert Cecil Potter, Newark, N. J., University of the City of New York Medical Department, 1893, member of the Medical Society of New Jersey, for many years on the staff of St. Michael's Hospital, aged 63, died, February 6

Bronislaw Jozef Nowierski, Yorktown, Texas, University of Missouri School of Medicine, Columbia, 1884, past president and secretary of the De Witt County Medical Society, aged 70, died, February 19, of chronic myocarditis

Julius Goldfinger, Cleveland, Cleveland College of Physicians and Surgeons, Medical Department of the University of Wooster, 1895, on the staff of the Fairview Park Hospital, aged 62, died, March 20, of heart disease

Leslie Grant Hill, Estherville, Iowa, Hahnemann Medical College and Hospital, Chicago, 1895, member of the Iowa State Medical Society, fellow of the American College of Surgeons, aged 65, died, February 24

Carl O. Larson, Superior, Wyo., Jefferson Medical College of Philadelphia, 1918, member of the Wyoming State Medical Society, aged 44, died, March 19, in Rochester, Minn., of tuberculosis of the kidney

Stanley J. Beckett, Chicago, Chicago Medical School, 1928, aged 33, died, May 9, in the Danish-American Hospital, of injuries received when the automobile in which he was driving was struck by a street car

William Penn Reese, Taylors Store, Va., University of Pennsylvania School of Medicine, Philadelphia, 1872, member of the Medical Society of Virginia, aged 86, died, February 15, of acute dilatation of the heart

Alexander H. Pearson, Hamburg, Mich., University of Michigan Medical School, Ann Arbor, 1904, served during the World War, aged 55, died, March 13, of acute nephritis, hypertension and arteriosclerosis

Robert Francis McLeod, Titusville, Fla., Bennett Medical College, Chicago, 1915, member of the Florida Medical Association, served during the World War aged 40, died, March 27, of acute dilatation of the heart

William Norrie Robertson, Toronto, Ont., Canada Victoria University Medical Department, Coburg, 1884, L.R.C.P., Edinburgh, L.R.C.S., Edinburgh, and L.F.P.S. Glasgow, 1885, aged 79, died February 19

Delvoss Houseworth, Douglasville, Ga., University of Georgia Medical Department, Augusta, 1895, secretary of the Douglas County Medical Society, aged 63, died, April 17, of carcinoma of the pancreas

Joseph Emanuel Larson, Chicago, Northwestern University Medical School, Chicago, 1909, aged 55, on the staff of the Roseland Community Hospital, where he died, April 24, of gastric ulcer

Obe Haight Hoag, San Francisco, College of Physicians and Surgeons of San Francisco, 1911, served during the World War, aged 63, died, March 3, in the Veterans' Administration Facility, Palo Alto

Robert O. Huffaker, Greeneville, Tenn., University of Louisville (Ky.) School of Medicine, 1892, aged 68, died April 19, in the Greeneville Hospital, of uremia, nephritis and myocarditis

Russell Davenport Walton, Frankfort, Maine, College of Physicians and Surgeons, Baltimore, 1902, served during the World War, aged 57, died, April 1, of cerebral embolus and mitral stenosis

Cheney Isaac Cole, Goffstown, N. H., Baltimore Medical College, 1896, member of the New Hampshire Medical Society, aged 68, died, February 26, of hypertension and chronic nephritis

John Fleming Goodchild, Toronto, Ont., Canada Queen's University Faculty of Medicine, Kingston, 1899, L.R.C.P. London, and M.R.C.S., London, 1904, died, April 27, of influenza

Franklin Cauthorn, Portland Ore., University of Missouri School of Medicine, Columbia, 1878, Jefferson Medical College of Philadelphia, 1879, aged 75, died, February 13, in Harmon N. Y.

John Nicholas Atheneos, New York, Columbia University College of Physicians and Surgeons, New York, 1933, aged 29, died May 7, in the Morrisania Hospital, of pneumonia

George E. Countryman, Aberdeen, S. D., Missouri Medical College, St. Louis, 1888, on the staff of St. Luke's Hospital, aged 69, died, April 24, of cerebral hemorrhage

Lewis Charles Robinhold, Auburn, Pa., Jefferson Medical College of Philadelphia, 1891, aged 64, died, March 9, of cardiovascular renal disease and bronchopneumonia

William Von Boenigk, Chicago, National Medical University, Chicago, 1909, on the staff of the Martha Washington Hospital, aged 60, died, May 9, of coronary thrombosis

Alfred S. Weiss, Lebanon, Pa., Medico-Chirurgical College of Philadelphia, 1903, on the staff of the Good Samaritan Hospital, aged 54, died, April 2, of coronary thrombosis

John George Crosby, New York, University of Arkansas School of Medicine, Little Rock, 1924, aged 41, died, February 1, in the Bellevue Hospital, of cerebral embolus

John W. Kinsinger, Vaughn, N. M., Cincinnati College of Medicine and Surgery, 1887, past president of the New Mexico Medical Society, aged 70, died, February 18

Walter W. Holladay, Porterville, Miss. (licensed in Mississippi in 1883), president of the Kemper County Medical Society, aged 77, died, January 12, of myocarditis

Valentine J. Yorty, Pittsburgh, Baltimore Medical College, 1906, member of the Medical Society of the State of Pennsylvania, aged 56, died, April 17, of fibrosarcoma

Charles Henri Ferguson, Toledo, Ohio, Toledo Medical College 1896, aged 70, died, April 25, in St. Vincent's Hospital, of cirrhosis of the liver and diabetes mellitus

Fordyce G. Gabbert, Casey Creek, Ky., University of Louisville School of Medicine, Philadelphia, 1909, aged 51, died, March 16, of pneumonia and heart disease

Birdie Eugenia McLain Springs Higginbotham, Chicago, Bennett Medical College, Chicago, 1912, aged 43, died, January 6, of toxemia, due to extensive burns

William Pardee Sprague, Los Angeles, Bellevue Hospital Medical College, New York, 1882, aged 73, died, March 19, of coronary thrombosis and arteriosclerosis

Marks Murray Waxman, New York, University and Bellevue Hospital Medical College, 1903, aged 50, died April 9, of heart disease, aboard the *Mauretania*

William Cooke Lester, Batesville, Miss., University of Louisville (Ky.) School of Medicine, 1911, served during the World War, aged 48, died, February 11

William Albert Holden, Pasadena, Calif., American Medical College, St. Louis, 1899, aged 74, died, April 1, in the Los Angeles General Hospital, of uremia

Alexander Reid, Umatilla, Ore., University of Oregon Medical School, Portland, 1896, aged 73, died, March 8 in Los Angeles, of carcinoma of the throat

William Wirt Jones, Dayton, N. Y., University of Buffalo School of Medicine, 1892, for many years health officer, aged 66, died, April 14 of myocarditis

Garrett Joseph Hickey, Northampton, Mass. University of Maryland School of Medicine Baltimore, 1893, aged 67, died, April 9, of cerebral hemorrhage

Frederick William Arlt, New Haven, Conn. University of Bellevue Hospital Medical College, New York 1906, aged 57, died, March 8, of heart disease

Paul Truitt Willis, Brooklyn Cornell University Medical College, New York, 1921, aged 37, died, March 27, of myocarditis and bronchopneumonia

Lucius Field Foote, Minneapolis, Chicago Medical College, 1877, aged 81, died, April 10, in the Hill Crest Surgical Hospital, of arteriosclerosis

LONGEVITY OF THE ERYTHROCYTE

To the Editor—In a recent editorial on the longevity of the erythrocyte (*THE JOURNAL*, April 21, p 1304) are quoted the results of studies made by Escobar and Baldwin, who found the life of the red blood cell to be from eighteen to thirty days. The method used by Escobar and Baldwin and also the other methods mentioned in the editorial are indirect and therefore may yield inconclusive results. There is a simple method for determining the life of an erythrocyte by means of which accurate results can be obtained but which is not mentioned in the editorial, namely, by tracing the fate of transfused blood cells.

In the editorial, the following statement was made: "Unfortunately, one cannot earmark an erythrocyte and follow its fate in the circulation or in some secluded organ." This is not entirely true, for there are certain natural "earmarks" by which the transfused red blood cell can be identified in the recipient's circulation, namely the agglutinogens A, B, M and N. The agglutinogens A and B are well known since on them depends the existence of the four Landsteiner blood groups, O, A, B, and AB, which are used as the basis for the selection of donors for blood transfusion. The agglutinogens M and N were discovered in 1927 by Landsteiner and Levine by using immune rabbit serum obtained after injecting human blood into rabbits. With the aid of the anti-M and anti-N reagents which they prepared, Landsteiner and Levine were able to differentiate three additional types of human blood: type M or M + N—(blood containing agglutinin M but not agglutinin N), type N or M—N + (blood containing only agglutinin N), and type MN or M + N + (blood containing both agglutinogens, M and N).

The technic used for tracing the fate of the transfused blood cell is simple, provided potent, specific anti-M and anti-N serums are available and the investigator has had sufficient experience in working with these reagents. Suppose for example, that donor and recipient both belong to group A, but the donor belongs to type M and the recipient to type N. Before the transfusion the recipient's blood naturally gave no reaction with the anti-M serum. After the transfusion, however, if a suspension of the recipient's blood is tested with anti-M serum there will be a partial agglutination, since the donor's blood in the patient's blood stream will react with the serum. This test may be repeated as frequently as desired, from day to day and from week to week. The time it takes for the recipient's blood to return to its original status, namely to give no trace of agglutination with the anti-M serum, is the maximum lifetime of the transfused blood cells. Using this method, Landsteiner, Levine and Jones (*Proc Soc Exper Biol & Med* 25 672 [May] 1928) were able to recognize transfused blood cells in a patient's circulation for more than seven weeks after the transfusion (no tests were made after that time). In a study on a series of ten cases, I have found that the life of the transfused blood cell probably averages between 80 and 120 days (unpublished observations).

If it is desired to trace the decrease in number of transfused blood cells from day to day, a simple modification of the technic is necessary. In the illustration given, in which type M blood is transfused into a type N individual, if, subsequent to the transfusion the blood cell suspension of the recipient is tested with anti-N serum all the blood cells except those derived from the donor will agglutinate. The unagglutinated cells can be counted as follows: Blood is taken as for a red blood cell count, using anti-N serum in place of the usual diluting fluid. The suspension obtained is transferred to a small test tube and allowed to stand for from two to three hours at room tempera-

ture (when the agglutination will be complete) The tube is then gently shaken until the unagglutinated cells are evenly suspended, and a small drop of the mixture is transferred to a counting chamber, care being taken to avoid the clumps Using this technic, I have found that the decrease in the number of transfused cells is directly proportional to the time, from one third to one fourth of the transfused blood disappearing each month This type of continuous decrease is to be expected under the assumption that all red blood cells have approximately the same duration of life, since naturally, the oldest cells will disappear first and the youngest survive the longest

The methods just described can be applied in any hospital where transfusions are performed, since the agglutinogens M and N play no part in transfusion reactions and therefore need not be taken into account when donors are selected for blood transfusions Transfusions of type M and MN blood into type N individuals, and of type N and MN blood into type M individuals, must therefore occur very frequently Even before the agglutinogens M and N were discovered, however, Winifred Ashby (*J Exper Med* 29 267 [March] 1919, *Arch Int Med* 34 481 [Oct] 1924) had used a similar method for determining the life of transfused blood cells, with the aid only of the four Landsteiner blood groups Ashby succeeded in demonstrating the presence of the blood of group O donors in the circulation of Group A and group B recipients for periods up to 100 days after transfusions, performed under the principle discovered by Ottenberg, that group O individuals can serve as universal donors for emergency transfusions Using Ashby's method, Wearn, Warren and Ames (*Arch Int Med* 29 527 [April] 1922) found that transfused blood may remain in circulation for periods of from 59 to 113 days, the average being 83 days

Curiously enough despite all this work most textbooks still give the life of the erythrocyte as thirty days

McDONAGH METHOD DISAVOWS MICRO-DYNAMICS

To the Editor —Your Bureau of Investigation rather belies its title in the reference it made to me and my work in THE JOURNAL, January 6 I am unaware of any investigation it has made of my work, in which I have been engaged for nearly thirty years, and had it done so it would not have made the misstatements it has Indeed, THE JOURNAL has always steadfastly refused to review my books and has done everything possible to prevent my views from becoming known Surely, investigation inside medicine would be more fruitful than outside medicine If medicine rendered the public the service it should, there would be no room for quacks If my attempts to place medicine on a sounder basis than it now stands are misjudged, it should be your duty to expose them before going further afield But your refusal to deal with what you fear is becoming a cult suggests they are right, in which case it is equally your duty to allow light to get at them

Theories are intricate and involved only when there is absence of desire to understand them In this case they are extraordinarily simple because not a single word has been coined to explain them, hence the mention of 'private nomenclature' is a misstatement of fact I am completely disinterested in any particular remedy and not one of the many I have introduced into medicine is proprietary, of secret composition, or carries a peculiar name Taking one of the remedies to which you refer, viz, 'S U P 36,' it is the best pyrexial antidote extant provided it is prescribed in time In measles, for example, it shortens the attack, reduces the malaise and prevents complica-

tions It can be made by any good chemist, its composition has been published in my writings since 1923, and the name is a contraction of its chemical nature, symmetrical urea of para benzoyl-para-amino-benzoyl-1 amino-8-naphthol 3 6 sodium sulphate I have nothing whatever to do with the introduction of "Antrypol"

J E R McDONAGH, London, England.

TRICHINA IN BLOOD

To the Editor —In THE JOURNAL, April 14, page 1249, in answer to the question of a New Jersey physician, reference was made to the demonstration of the larval form of the trichina in the circulating blood, as follows

The first and apparently so far the only other demonstration of trichinous larvae in the circulating blood in man is by W W Herrick and Theodore C Janeway (Demonstration of Trichinella Spiralis in the Circulating Blood in Man *Arch Int Med* 3 263 [April] 1909) who found them in fresh samples of blood after taking with 3 per cent acetic acid

In the *New England Journal of Medicine* (201 816 [Oct. 24] 1929) I reported a case with Dr Ralph E Bicknell in which the larval form of the trichina was demonstrated in the fresh samples of blood by the same technic

S SEYMOUR HORLICK, M D, Boston.

STAPHYLOCOCCUS TOXOID

To the Editor —May we offer the following data to support the conclusions reached by Kindel and Costello in their study of staphylococcus toxoid in the treatment of pustular dermatoses (THE JOURNAL, April 21, p 1287) We, too, have treated but a small number of patients but our results, like theirs, were so definitely unsatisfactory that we feel impelled to record them, especially since commercially prepared toxoids are gaining wide use Our patients were from the Department of Dermatology, University of Illinois College of Medicine We treated about fifty patients, of whom only twenty three received the minimum dosage recommended by Dolman This group included twelve cases of pustular acne vulgaris, five of sycosis barbae coccigenica, four of furunculosis, one of pustular folliculitis of the scalp and one of dissecting cellulitis of the scalp (perifolliculitis capitis abscedens et suffodiens) The toxoid material was prepared essentially according to the specifications outlined by Kindel and Costello We used weaker concentrations than did they, but in larger volumes, injected subcutaneously Of the twelve patients with acne, three showed some improvement but did not get well, seven were unaffected and two definitely became worse The injections were given twice each week, in one case for four months, and the average number of injections was twelve There was no noticeable improvement in any of the patients with sycosis barbae or in the two patients with scalp lesions These received an average of eighteen treatments and as a group they seemed to show milder local reactions to the injections Of the four patients with furunculosis, two were not influenced by the toxoid and two responded promptly and favorably Of the latter, one returned in six weeks with a recurrence These patients received an average of nine injections They showed local reactions to a greater degree than did the other patients, and we too noticed that in all our cases the local reactions became lessened with succeeding injections In two instances there were systemic reactions with slight rise of temperature, muscle pains and malaise One man with recurrent furuncles while under treatment, and after he had received an "adequate number of injections in the arms, developed a huge carbuncle on the thigh, which required surgical intervention

The results in our other patients were equally disappointing certainly they were far less satisfactory than with the usual methods of treatment We are aware that favorable

results have been reported elsewhere, but our observations so paralleled those of Kundel and Costello that we thoroughly endorse their recommendation to the profession that caution be exercised against becoming overenthusiastic about the value of staphylococcus toxoid until much more study has been made

Queries and Minor Notes

ANONYMOUS COMMUNICATIONS and queries on postal cards will not be noticed. Every letter must contain the writer's name and address but these will be omitted on request.

CORONARY THROMBOSIS ASSOCIATED WITH FALL IN BLOOD PRESSURE

To the Editor—A woman aged 56 has had a blood pressure averaging 200 systolic for at least five years. Three months ago she had an attack during which her pulse rose to 120 but was regular except for an occasional extrasystole. The pressure first dropped to 170/80 and then to 130/80. There was no decrease in urinary output and the only subjective signs were liver tenderness and gastric disturbances. Of course she is digitalized and her pulse varies between 70 and 80, never lower. The urine contained a few hyaline casts at first but now is normal. Hemoglobin is 86 per cent and blood pressure remains at 130/80. How long would you keep this patient in bed and what would be the guide in allowing her to return to restricted activities? At present she has no complaints. I would sincerely appreciate your discussion. Please omit name.

M D California

ANSWER—It is difficult to evaluate properly the information given, because some most significant facts are omitted. The height of the diastolic tension prior to the attack is important. It is also notable that no mention is made of dyspnea, or perhaps change of color, at the time of the attack. Three possible explanations of the acute attack can be considered on the basis of the data at hand: (1) acute relative hypotension with the cardiac manifestations secondary, (2) cardiac decompensation, and (3) coronary occlusion.

Not knowing the height of the diastolic tension before the acute disturbance, it is impossible to do more than include the first hypothesis among the possibilities. It is well known that any abrupt reduction of the arterial tension, as sometimes occurs in spastic hyperpiesis, induces a notable tachycardia through a reflex by way of the sensory fibers in the aorta and that, inversely, a rise in arterial tension is accompanied by a bradycardia. However, there is no history to indicate that sudden reduction of the arterial tension was the primary phenomenon. Furthermore, with exceptions, such acute periods of relative hypotension are transient unless due to a fundamental cardiac change. Cardiac decompensation occurring because of myocardial exhaustion secondary to the hypertensive disease is rarely so acute in onset and almost invariably presents the typical picture of congestive cardiac decompensation marked dependent edema, dyspnea, pulmonary edema and gross hepatic engorgement. The description of the attack is by no means characteristic of such a clinical picture.

Coronary occlusion is the most logical diagnosis on the basis of the facts as presented. Perhaps one of the most significant diagnostic points in coronary thrombosis is a rapid and prolonged fall in arterial tension. When present, a pericardial friction rub is pathognomonic and is usually heard within the first twelve hours. Coronary thrombosis without pain is not rare, many reports of such instances have appeared in the literature, the accuracy of the diagnoses having been confirmed by necropsy. Many minor attacks, involving small branches of the coronary vessels, may be wholly asymptomatic and result in gradual replacement with collagenic connective tissue, chronic fibrous myocarditis or myocardosis. When pain does occur in coronary thrombosis it is frequently unlike that seen in angina pectoris, being more commonly referred to the upper part of the abdomen and the epigastric area. This patient presented such complaints.

As yet no fully satisfactory explanation has been presented of the acute, marked and often persistent drop in arterial tension associated with coronary accidents. This fall differs from that observed in congestive heart failure in the rapidity of the fall and especially in the marked reduction of the diastolic tension. In congestive failure prior to actual decompensation or during the period of low cardiac reserve, a slowly falling systolic ten-

sion with a relatively fixed diastolic tension has long been recognized as a sign of impending cardiac exhaustion, particularly in hypertensive disease. It is quite obvious that here the change in tension must have involved the diastolic as notably as the systolic tension. It is presumed, and on significant evidence, that this characteristic acute relative hypotension occurring with coronary thrombosis is largely reflex in origin. It closely resembles true shock in its mechanism. It is only through extensive arteriolar dilatation that such marked reduction in the diastolic tension is possible, the route of the cardiac-arteriolar reflex is unknown.

It may perhaps be pertinent to emphasize the fact that despite the long habituation to extensive hypertension there was little if any evidence of renal impairment resulting from the relative hypotension. The arterial tension after the attack was relatively low for this particular patient, although well within the normal range. The transient appearance of a few hyaline casts does not imply that the fall in arterial tension caused them; rather there may have been a mild proteinuria and casts in the urine for some time prior to the attack (as is common in hypertensive disease), which persisted for a short time after the reduction in arterial tension. Here, then, is another of a great many clinical examples illustrating that even marked reduction of the arterial tension does not result in renal functional inadequacy. It is the contention of Whipple that the state of hypertension is largely a compensatory mechanism to maintain an adequate renal circulation and that reduction to normal levels is dangerous from the point of view of inducing renal failure thereby. Repeated clinical observations contradict this contention, especially when the reduction in arterial tension is relatively gradual. It can be said that in most instances the renal circulation is not more efficient in hypertensive individuals but less so, and with reduction of the excessive hypertension there is improvement in the renal function and therefore, presumably, also of the renal circulation.

The present status of the patient appears to be good, but such freedom from symptoms may be misleading. On the quite justified assumption (no more is possible with the data on hand) that the attack consisted in a coronary thrombosis, the most significant therapeutic measure available is rest, especially prolonged rest. Confirmation of the diagnosis and evaluation of the approximate extent of injury might be greatly aided by electrocardiographic study. To rely wholly on the electrocardiogram, however, would be most unwise. If the patient has been in bed for three months, as suggested by the query, that should suffice for the period of absolute bed rest. Repair and rehabilitation take time and the older the person the longer is the time required for repair. Her activity should be resumed very gradually, the extent of activity being based largely on the cardiac response to increased effort. After all, as Sir James Mackenzie declared, it is the ability to respond to an increased burden that best measures the degree of cardiac reserve. At present, with a normal pulse rate, full digitalization is not necessary or desirable, but small doses of digitalis for some months may be of value as was recently reemphasized by Christian. The continuous administration of some of the theobromine coronary dilators, such as theophylline-ethylenediamine or theophylline-calcium salicylate offers perhaps some prophylactic protection against recurrence.

BENIGN OR ESSENTIAL HYPERTENSION

To the Editor—I have recently heard the term "benign hypertension." In none of my textbooks on medicine and medical diagnosis was I able to find this condition mentioned or otherwise discussed. I shall be much indebted for any information you may give me briefly on the subject. Kindly omit name.

M D Connecticut

ANSWER—The term "benign hypertension" has been loosely used to be more or less synonymous with "essential hypertension." For many years it was thought that there were two types of arterial hypertension: the type associated with extensive renal injury and renal functional impairment and the form in which the hypertensive changes existed independent of any demonstrable gross renal impairment. The latter type has often been loosely and really incorrectly termed "benign hypertension" or "essential hypertension." It is now known, and generally conceded, that there is but one fundamental form of hypertensive disease, which may or may not be associated with extensive nephritis (Fishberg, A. M. *The Arteriolar Lesions of Glomerulonephritis*, *Arch Int Med* 40:80 [July] 1927). Naturally, when nephritis coexists as a complication the prognosis is distinctly darker and therefore the situation may then be considered as less "benign." In more recent years the term "malignant hypertension" has been introduced to designate that type of arterial disease characterized by a rapidly progressive arterial degeneration and a relatively short course before fatal

termination. Careful studies (Keith, N. M., Wagener, H. P., and Kernohan, J. W. The Syndrome of Malignant Hypertension, *Arch. Int. Med.* 41: 141 [Feb.] 1928) have revealed no fundamental differences in the processes of this "malignant" form except for the rate of progression. As yet no adequate explanation of this difference has been presented. Perhaps the term "benign hypertension" was employed to contrast this so-called malignant form.

In the pathogenesis of hypertensive disease (Stueglitz, E. J. Arterial Hypertension, New York, Paul B. Hoeber, Inc., 1930) the arterioles are first intermittently spastic, later continuous hypertonicity occurs and still later degeneration of the arteriolar musculature permits of fibrotic scarring, so that the end-result is an extensive arteriosclerosis. Thus the single disease progresses through various phases, early in the course the changes are reversible and are amenable to therapeutic correction, later, when fibrotic scarring has occurred, the changes are irreversible, irrevocable and not amenable to therapy. In a single individual in different stages of the disease the situation shifts slowly from a potential threat to a permanent irrevocable injury, early the disease may be considered "benign," but unless the processes are interrupted the progression is onward to more and more severe permanent injury. It is felt that the use of the terms "benign" or "essential" hypertension is distinctly undesirable, as they are both misleading and do not rest on a firm scientific foundation. It must be emphasized that hypertensive arterial disease has a distinctive consistent pathogenesis and that in this progression of changes the clinical, pathologic and physiologic states gradually change.

ARTHUR PHENOMENON OR LOCAL ANAPHYLAXIS

To the Editor—I wish to report an unusual series of reactions following the use of typhoid paratyphoid vaccine. A boy aged 8 years was given 0.25 cc of the vaccine with nothing unusual happening until about the fourth day when a localized abscess about 2 cm in diameter formed on the arm. This was opened and drained since it was thought at the time that the aseptic technic might have been at fault. However when the same thing occurred following a second dose of about 0.35 cc given with extreme precautions I felt quite sure that I was dealing with an unusual reaction of the tissues. This abscess was not opened and was absorbed in about two weeks. Following the third dose of about 0.5 cc there was a moderately severe systemic reaction, a general malaise lasting from two to three days. This time the local reaction was more severe than ever—an abscess about 4 cm in diameter. This ruptured spontaneously when the youngster had a fall. After that the arm healed up rather quickly and no further vaccine was given at the time. Three other patients were immunized with vaccine from the same vial used for this patient with no unusual reactions. Dec. 19, 1933 the same patient, now a young man of 18 was given 0.1 cc of the vaccine with the idea of starting out cautiously and avoiding untoward reactions. A week later he had quite a swelling on his arm—about 2 cm in diameter, not painful—which looks to be another sterile abscess. There was no systemic reaction noted. Will you please give us your opinion of the nature of these reactions, tell me of other reported cases and advise me about the advisability of further immunizing doses. Please omit name. M. D. California

ANSWER—The description of sterile abscess formations at the site of typhoid inoculations is that of the Arthus phenomenon, or local anaphylaxis. It is exceedingly uncommon in typhoid injections, also in other protective injections, except when serum is used. It is more common in such instances, and a number of instances following antiserum injections have been reported.

HEMIATROPHY OR ARRESTED DEVELOPMENT OF BODY

To the Editor—A man aged 43, 5 feet 8 inches (173 cm) in height complains of severe pains in the right shoulder and arm present for a period of two years. The patient shows a distinctly smaller left half of the body including the face, upper and lower extremities and chest; the upper extremities being not only smaller but also shorter. The left nipple is present but there is no breast although the right breast is unusually well developed. There is no paralysis or previous history of disease to account for this condition which has been evident from early childhood if not from birth. Blood urine and all neurologic examinations are otherwise negative. Roentgen examination of the spine, shoulder and joint is negative. Cholecystography gives negative results. Roentgen examination revealed a mediastinal mass, probable an aortic aneurysm. What is the disease and what is the cause of the lack of development of an entire half of the body? Kindly omit name. M. D. New York

ANSWER—No doubt the changes in the mediastinum will explain the pain referred to in the shoulder and arm.

The central nervous system is not myelinated until one or two years after birth. Injuries during birth or in early infancy are therefore more likely to be permanent.

Cerebral hemorrhages are known to be rather common at birth and might explain the condition of asymmetry. They

most commonly produce spastic paraplegia, although there may be symptoms without spasticity.

The diagnosis in this case would probably come under congenital muscular deficiency or early arrest of growth caused by injury or infection. In the first condition, lack of development of a portion of the brain itself might be present, but one would expect to find some mental changes or perhaps epilepsy. In the latter condition, birth injury would be the most likely cause in absence of a history of illness preceding the arrested development.

The asymmetry is also similar to that present in progressive hemiatrophy, or Romberg's disease. The onset here is usually after ten years of age, although it has been recorded as being congenital. The symptoms are those of progressive atrophy and not arrested development, although the congenital type might be difficult to rule out. However, the trophic changes are quite extensive in hemiatrophy. It is usually limited to the face, especially in the region supplied by the fifth nerve.

The location of the lesion in hemiatrophy is probably in the sympathetic nervous system but may be in either the central or the peripheral portion. The cause has not been determined from the few necropsies performed.

Hemiatrophy is closely related to scleroderma.

In the case described there are probably some pathologic changes in the sympathetic nervous system the nature and actual site of which cannot be accurately surmised from present knowledge.

PREVENTION OF VENEREAL DISEASE AND CONCEPTION AFTER RAPE

To the Editor—Please give me information regarding the best approved technic to follow after rape to prevent venereal disease and if possible to prevent conception. Has such a procedure ever been worked out with accuracy similar to the methods used to prevent venereal disease after exposure in men? I have no specific case in mind but would like to be prepared to the best of my ability, to combat such conditions. It is evident that at least three types of precaution should be taken: (1) against gonorrhea, (2) against syphilis, (3) against conception. Please discuss fully. Has any progress been made in any states toward legalizing properly carried out abortions if conception occurs after rape? Please omit name. M. D., California

ANSWER—No technic has been worked out to prevent venereal disease and conception following rape, chiefly because instances of true rape are seen infrequently. Most instances of so-called rape do not come within the definition of rape, namely, "carnal knowledge of a woman by a man accomplished by force and against her will." Children especially are prone to make false accusations, but adult women also make false charges occasionally.

Usually a case of rape is not seen for at least a few hours after the crime has been committed. At this time little can be done to prevent conception because in nearly all instances in which conception takes place the fertilizing spermatozoon gains access to the uterine cavity within a few minutes after coitus. It reaches the fallopian tube shortly afterward but even if it did not it is possible, though hardly likely, that a curettage performed when the patient is first seen will help. For a curettage to be effective in such a case, every bit of endometrium above the basalis must be thoroughly removed and also all the spermatozoa in the uterine cavity. Should a spermatozoon succeed in fertilizing an ovum in spite of a curettage, it is possible for the ovum to find a sufficiently prepared endometrium for embedding because it usually takes about ten days from the time of coitus to the time of implantation in the endometrium. It may be dangerous to perform a curettage immediately after rape, because not infrequently the offender has gonorrhea. Smears should, of course, always be made of the vaginal contents to see whether gonococci are present. If such organisms are found, a curettage is contra-indicated. If the smears fail to show gonococci, this does not imply the absence of gonorrhea. The disease may not manifest itself until a number of days later. Evidences of syphilis will surely be absent if the woman did not have the disease before the rape was perpetrated, even though the offender has active syphilis, because of the incubation period of syphilis.

When a case of rape is seen, one should obtain careful information about the exact time of occurrence of the crime and make a thorough examination not only of the external genitalia and surrounding tissue but also of the entire body for marks of violence. It is necessary for the physician to know this information because he will undoubtedly be asked about these facts in court. Smears should be made of any discharge seen on the external genitals and also the contents obtained from the vagina. Careful notes should be made of the character of the vaginal contents, especially as to whether spermatozoa, blood and pus cells are present. Immediately after all the examina-

tions have been made, the vagina should be irrigated with a weak mercuric chloride or potassium permanganate solution. Then the entire vagina but especially the region of the Bartholin gland ducts, the cervix and the urethra should be swabbed with a 2 per cent silver nitrate solution. In addition, one of the prophylactics used by men for syphilis, such as 33 per cent ointment of mild mercurous chloride, should be used on the external genitalia, in the vagina, on the external urethral orifice and on the cervix. Two weeks later and again at four weeks smears should be made from the cervix, vagina and urethra, and blood should be subjected to a Wassermann or Kahn test. If the blood test is positive, another test should be made to verify it. If the Wassermann or Kahn test is negative, three more tests should be made at intervals of three weeks.

As far as is known, no state in this country has made provisions for the induction of abortion in cases of rape.

ETIOLOGY OF SWELLING OF ARM

To the Editor—A man aged 25 a clerk in a local grocery store whom I have known since childhood whose habits are good and who has no history of disease excepting that his father died of diabetic coma has enjoyed good health all his life. Dec 26 1933 he came to me with his left arm swollen from the deltoid down to the tip and a little cyanosed, with a little ache in the elbow. A roentgenogram of the elbow gives negative results. Since that he has responded to rest and carrying the arm in sling, but it remains swollen and a little boggy like, hardly boggy but with a little boggy feel. Then there have appeared since some crows feet blood vessels round the inside of the deltoid. His brother says that he took a strong hold of his arm not hard but just firm but he does not think that would cause it. He does not recall hurting it but he did handle 100 pound sacks of sugar during the holiday rush and noticed that the arm became somewhat tired. He may have strained it. I made a diagnosis of phlebitis of the arm although I have never seen a case like it in my thirty four years of practice. I wish that you would advise me as to whether this condition occurs in the arm. I have never seen one. He has a good grip on both hands. This has been reported as a compensation case and I wish to know whether my grounds are correct. Please omit name. MD Minnesota

ANSWER—The swelling of the arm might be due to a number of conditions.

A slight rupture of some muscle fibers or rupture of a blood vessel in the muscle or under the fascia would produce the symptoms described. A complete rupture of the long head of the biceps tendon occasionally occurs from a severe muscular effort.

Phlebitis may occur in the arm. This condition would involve the entire distal portion of the extremity with edema of the forearm. There should be some evidence of inflammation with tenderness along the veins. Some focus of infection is usually present.

While the possibility of a neoplasm in this case is rather slight one must bear in mind the occurrence of a sarcoma with the dilated veins described.

Either phlebitis or a deep hematoma might produce peripheral swelling of the extremity. Evidence of inflammation locally and of general symptoms should differentiate them. An increased leukocyte count with an increased percentage of polymorphonuclears would speak for phlebitis.

In the absence of a neoplasm or a history of a definite injury preceding the symptoms, the evidence of the heavy work described should establish it as a case for compensation.

USE OF TUBERCULIN SKIN TEST

To the Editor—What is the present consensus relative to the value of the routine use of the tuberculin skin test? What beneficial knowledge either to the individual or to the physician would be derived by giving the tuberculin cutaneous test as a routine procedure in identical dosage to school children of various ages and degrees of hypersensitivity? From my limited experience such testing is of no value and may do harm to the susceptible child. Please omit name. MD Texas

ANSWER—Physicians who have had an extensive experience with the use of the tuberculin skin test are enthusiastic about its value. There are two beneficial facts obtained from a positive test. First the person reacting has been exposed either directly or indirectly to some person or some animal suffering from tuberculosis or acting as a carrier and spreader of tubercle bacilli. Seeking this source often results in finding an open case of tuberculosis in a person not previously suspected of having the disease. The finding of such a case may be of great benefit to the patient since his disease may not have reached too advanced a stage for successful treatment. Even if it cannot be treated successfully isolation or teaching methods of prevention of spread may save the family and community from contamination with tubercle bacilli from that particular source.

Second the individual who reacted positively to the test is known to have a focus of tuberculosis somewhere in his body.

This focus may harbor living and virulent tubercle bacilli over many years or even a lifetime. The positive test establishes the fact that the tissues are sensitive or allergic to the products of growth of tubercle bacilli. Allergy is a dangerous factor, therefore the person who reacts positively to the test although he may appear in perfect health at the time, is a potential case of a reinfection type of tuberculosis from either exogenous or endogenous sources.

These facts make the routine administration of tuberculin tests to children of various ages and degrees of hypersensitiveness of great value, since a negative reactor may become a positive reactor after a subsequent exposure to tuberculosis. In many parts of the country not more than 10 or 20 per cent of children of school age have been contaminated with tubercle bacilli. Obviously, the lower this incidence becomes the more valuable is the selectivity of the test.

Identical dosage is necessary so that a standard is set up, the deviation from which gives a measure of the individual's reaction. The dose of tuberculin used in testing school children causes no harm whatever, even if the child has a reinfection type of disease.

DANGERS TO WORKERS IN NITROCELLULOSE SOLVENTS

To the Editor—A primipara aged 18 employed in a bakelite factory working in nitrocellulose solvents (amyl and ethyl acetate) developed oliguria and albuminuria without casts a blood pressure of 96 systolic, 46 diastolic and a mild secondary anemia. Her work in a close room amid the fumes arising from these solvents requires her to keep her ungloved hands more or less constantly wet with this solution. Is it to be regarded as probable that these chemicals are etiologic factors in this nephrosis? RICHARD BARTLETT OLESON, M D, Lombard Ill

ANSWER—If amyl and ethyl acetates were the only solvents of bakelite to which exposure was provided, it might be doubted whether the clinical condition described should be attributed to these substances as the cause. The toxicity of these agents is at this time believed to be limited to the production of a mild inflammation of the eyes, nose, throat and bronchi. However, it is frequently true that solvents other than those mentioned are employed in the procurement of the solution of the bakelite resin. In the past, benzene (benzol) has been extensively used. Methanol has been considered a practical solvent for bakelite and possibly has been so used. In either case the condition described might have been brought about as an occupational disorder. Differential blood counts in which a leukopenia is detected would suggest the possibility of benzene poisoning. The detection of wood alcohol or its decomposition products in the urine would tend to place responsibility on that agent as a causative factor. Further inquiry should be made as to the solvents other than amyl and ethyl acetates and, unless others of greater toxicity are established, belief that the condition described is of occupational origin seems unwarranted.

USE OF SODIUM HYPOCHLORITE IN INFECTED WOUNDS

To the Editor—Please give me the correct technique for using sodium hypochlorite solution in the irrigation of infected wounds.

L A CROWELL JR M D, Lincolnton N C

ANSWER—Sodium hypochlorite solution should contain between 0.45 and 0.50 per cent of available chlorine. If it is below that it is too weak and if it is above that it is too caustic.

An apparently satisfactory preparation is known as hychlorite, described in New and Nonofficial Remedies, 1933, page 216. When diluted with seven volumes of water, the solution has the same available chlorine content as surgical solution of chlorinated soda and is isotonic. It deteriorates at the rate of about 12 per cent a year.

A preliminary cleansing of the skin and the wound is necessary. Excision of all lacerated or devitalized tissue should be done. All pockets of the wound should be explored and Carrel rubber tubes introduced for instillation of the solution. Ordinarily, counterdrains are not required.

The drainage tubes are of fine pure rubber, approximately 15 to 25 cm long, having a diameter of 5 mm and a lumen of 3 mm. The ends are tied off with linen or silk and, beginning at the distal end, from six to twelve small holes, approximately 0.5 mm in diameter, are pierced at intervals of 0.5 cm. One may make these with a special punch, going through the two sides at the same time and staggering the direction.

The number of tubes used must be decided by the size and depth of the wound. All parts of the wound should be bathed by the solution coming out of the tubes. To prevent the tubes

from bunching in the wound, strips of gauze are placed between them, which also helps to retain the solution

For superficial wounds, the Carrel tubes are covered with Turkish toweling and strips of gauze are placed between the tubes. A large pad of nonabsorbent cotton may be placed around the extremity. Simple wet compresses are sometimes used and changed frequently in superficial wounds.

The skin should be protected by covering with strips of gauze impregnated with petrolatum

At present, intermittent irrigation every two hours day and night with just enough solution to fill the wound has been most satisfactory. This is not always possible, and good results may be obtained by less frequent irrigation, although it is not so efficient in sterilization.

The wound should be redressed daily, the skin being cleansed and the tubes renewed. In certain conditions the change of dressings may be delayed for two or three days, provided the irrigations are kept up.

Bacteriologic films are made of the wound discharge from day to day and, when sterile, deep wounds may be sutured

OTOSCLEROSIS

To the Editor—A patient aged 30 is suffering from otosclerosis of two and a half years duration. Blood chemistry, the Wassermann reaction and other laboratory tests are all negative. A coexisting catarh has cleared up under instillation catheter infusion and the application of silver nitrate. Is there anything that will help to check the otosclerosis? Is radium applied through the external auditory meatus of any value in checking the progress of the disease? Is radium harmful? Please omit name.

MD New York

ANSWER—The etiology of otosclerosis is still unknown, despite the extensive research that is being conducted regarding this problem in a number of centers throughout the world. Nothing definite has been developed regarding the therapy, so that it is impossible to state definitely what can be done to check the progress of the disease. Radium, x-rays and other measures have been used to date but none have given any definite result regarding either the arresting of the disease or its cure.

ABSENCE OF ULVIA

To the Editor—In the routine examination of school children I have noticed absence of the uvula in many that have had their tonsils removed. I have noticed this in several cases of my own in which I felt certain that I did not accidentally include the uvula in removing the tonsil. Can this disappearance of the uvula following tonsillectomy be explained in any other manner than accidental removal? Kindly omit name

MD New York

ANSWER—Spontaneous disappearance of the uvula has never been recorded. As a rule when the loss of the uvula is noted after tonsillectomy the uvula has been inadvertently caught in the snare during the removal of the tonsil. However, its ablation is of no significance as long as no other portion of the soft palate is removed. Aside from operative procedure, it is not likely that there would be disappearance of the uvula unless some ulcerative process destroyed the tissue.

DISCHARGE OF SYPHILITIC PATIENT FROM TREATMENT

To the Editor —An automobile mechanic aged 34 who consulted me June 28 1932 was very nervous and with a symmetrically enlarged thyroid the blood pressure was 90 systolic 60 diastolic the pulse rate was 105 the temperature was normal I put him on tincture of iodine twenty drops three times a day July 14 his systolic blood pressure was 110 diastolic 60 pulse 95, temperature normal September 15 he came with a hard chancre on the penis but refused to have a blood test made October 27 he returned still with a chancre, and allowed a blood test to be made Kolmer's Wassermann test was 4442 — and the Wassermann reaction was 2 plus I gave him bismuth salicylate in oil October 27 and ordered daily inunctions with mercurial ointment also saturated solution of potassium iodide to toleration Beginning October 29 I gave him one injection of neoparsaphenine 0.3 Gm and three other doses of 0.6 Gm at intervals of five days owing to the smallness of his veins which caused trouble to get into them After the fourth dose I switched to bismuth in oil at intervals of five days and kept it up until Jan 7 1933 when I had another Wassermann test made which was reported negative I then stopped all injections but kept him on the inunctions and potassium iodide until the first of July having Wassermann tests made every month up to July 1 all being negative as was the test Oct 1 1933 and Jan 1 1934 He is apparently in excellent health at present and is not taking any medicine A Wassermann test of his wife was returned negative at the time he first came in Will you be good enough to advise me what I should say to a patient with the foregoing history Please omit name

M D Maryland

MD Maryland

ANSWER—The patient should be told that he is clinically and serologically well but that he should be kept under observation for several years with periodic blood tests and careful physical check ups. A spinal fluid examination is an additional

safeguard and should be done some time during the second year. One should hesitate to employ the word "cure" in cases of syphilis in which treatment was started in the primary sero-positive stage, as it has been frequently stressed that the golden opportunity for a cure is in the primary seronegative period. Nevertheless this patent apparently has what might be termed an abortive cure. Unless there is a clinical or serologic relapse, further treatment will probably not be necessary.

TREATMENT OF MASTURBATION BY OPERATION ON NERVE

To the Editor—I read an article in the Cincinnati *Lancet-Clin.* (n s 37 1896) by J H McCassy M D about the excision of certain nerves of the penis as a cure for masturbation in young men. In some cases he advises division of the dorsal nerve of the penis. He also says that the nerve can be cut and be made to reunite after a time as long as from two to three years. Dogs and horses treated in this way regained their sexual power. Could you tell me a physician preferably near here who has done this operation? Also is the vas deferens ever cut for this purpose and with what success? Who does this? Please omit name

MD, Ohio.

ANSWER—The operation referred to is technically quite simple and any genito-urinary surgeon could perform it. There are many excellent specialists in Cleveland. We doubt, however, whether any specialist would today perform this operation for masturbation. It is not mentioned in any modern works on the subject. In the first place it is entirely too hazardous, as one could not at all be certain that the nerves would reunite and if they do not the condition of impotence that might follow would be more serious than the original condition. In the second place masturbation can at present be treated with most satisfactory results by gentle prostatic massage and installations of weak silver nitrate solutions (from 1,000 to 1,500) with the Bangs sound syringe without taking any such serious risks as the operation mentioned. The vas deferens is never cut for this condition as it would do no good.

WASSERMANN FAST SYPHILIS

To the Editor—A married woman aged 28 has been under treatment by me for syphilis for the past two years. The source of the infection is unknown but the husband has been treated in a government hospital for dementia paralytica and is well at present. The husband states that he has no knowledge of a primary infection. The wife has no knowledge of a primary lesion and never had secondaries. From Feb. 6, 1932 to the present date she has had almost continuous treatment but presents a positive reaction at all times. I have given her six courses consisting of eight injections of neoparsphenamine from 0.3 to 0.6 Gm. and the first course of a bismuth compound. Ten injections of iodobismutol were given concurrently. Each course was of about two months duration with intervals of one or two months between courses. During the which she was given saturated solution of potassium iodide. On the last course I substituted silver arsphenamine from 0.15 to 0.25 Gm. After the fifth course I also gave her four injections of sodium thio sulphate. All told she has had forty injections of neoparsphenamine, eight of silver arsphenamine and sixty six of a bismuth compound. The Wassermann Kahn and Rosenthal reactions have remained persistently 3 plus and 4 plus until at the end of the last series with silver arsphenamine when the report was 2 plus. Spinal Wassermann colloidal gold and globulin tests give negative results. Her blood pressure is 104 systolic 70 diastolic. The heart and lungs are normal. No abnormal sensory reflexes are present and she feels quite well in all respects. In 1932 she weighed from 102 to 104 pounds (about 47 Kg.) at present she weighs 111 pounds (50 Kg.). In your opinion has she had sufficient treatment? Would you consider this a Wassermann fast case? Should I advise persistent treatment until at least one negative reaction has been obtained? Should silver arsphenamine be continued since the Wassermann reaction was 2 plus after its use in spite of the peculiar reaction she had with each injection especially with the larger dose of 0.25 Gm. During and following the injection she experienced a nervousness and faint tongue checks and lips rapid pulse a feeling of nervousness and fainting and crying. This would subside in about three to five minutes leaving no after effects. The injections were given slowly and carefully. Thank you for any suggestions you may give me. Please omit name.

M.D. Brooklyn

M D Brooklyn

ANSWER—The amount of treatment that has been administered in this case over a period of two years is adequate. The persistent positive serologic reaction would bring this into the category of Wassermann-fast cases. The Wassermann test should be considered only as one symptom of the disease and continuous treatment might prove detrimental to the patient's health. Intermitent treatment consisting of a short course of one of the arsphenamines, with a bismuth or mercury compound conjointly followed by iodides and a long rest period without any medication might bring about a reversal of the Wassermann reaction. There is no accepted criterion of treatment for a Wassermann-fast case. Further treatment with silver arsphenamine in view of the peculiar reaction experienced by the patient would not be advisable. Bismuth arsphenamine sulfonate (bismarsen) intramuscularly would be a good substitute.

HOSPITAL MEDICAL LIBRARY SUGGESTIONS

Prepared by the Council on Medical Education
and Hospitals

The "Essentials in a Hospital Approved for Interns" con-
tains the following provision

There must be a working medical library, in charge of a
librarian, which should contain a useful selection of late edi-
tions of standard text and reference books and current files of
not less than ten of the better medical journals. The library
should be inside the hospital building and be located where it
is readily accessible to the interns and staff members. Collec-
tions of choice reference books in pathology and clinical diag-
nosis and in roentgen-ray work should be found respectively
in the pathologic and roentgenologic departments."

Included in the "Essentials in a Hospital Approved for
Residencies in Specialties" is the following medical library
requirement

"The hospital shall maintain, or provide ready access to,
an adequate medical library containing modern texts and cur-
rent journals covering the fields in which residencies are
offered"

Since the internship must now be considered as the fifth
year in medicine and approved residencies in specialties as
postgraduate work, hospitals on such educational bases should
provide adequate medical libraries

While it is impossible for all hospitals to be possessed of
an ideal library such as may be found in a medical school and
in some of the large teaching hospitals, there are few hospi-
tals that cannot maintain a library of a few choice medical
periodicals, standard texts and reference books

The important function of a medical library in a hospital
is to provide attending physicians and interns with material
for immediate reference and consultation, intensive study of
the patients in the hospital, and the preparation of papers,
discourses and special reports to be used in staff meetings,
medical gatherings and for publication. Through the library
service, both the interns and the regular staff are provided
with a means of professional growth and are inspired to
greater zest and thoroughness in their work

Organization

The medical library should be under the supervision of a
committee consisting of several members of the staff. Many
library committees are such in name only and care should be
exercised in order to assure the inclusion of such doctors as
would take an active interest in developing the library. The
funds for regular additions to the library should be placed at
the disposal of this committee

The hospital that has no library may establish one by various
means (a) by an annual appropriation (as little as \$300 annu-
ally would be sufficient for establishment and expansion), (b)
by annual subscription from staff members, or (c) through
gift or endowment in the manner that other equipment and
furnishings are given a hospital. A good nucleus no matter
how small, and an assured annual income are the essential
requisites of the hospital just beginning its medical library.
By the gradual addition of material from year to year a library
would be evolved that could be considered an asset to the
institution and the community

The cost of maintaining the library already established is
not prohibitive and could be made a legitimate item in the
operating budget. When this cannot be done, an excellent plan
is for each member of the medical staff to contribute at least
a small sum annually toward maintaining and improving the
library and this amount could be made a part of the staff dues

It is desirable that the library should be immediately in
charge of a librarian who has had training and experience in
library work. In the absence of an experienced librarian, some
competent person frequently the superintendent or record clerk
or some other person selected from among the regular admin-
istrative personnel, should be placed in charge

A code of library regulations should be drawn up by the
library committee and should be carefully adhered to by the
staff members. In general, books or periodicals should not be
removed from the library, if this is unavoidable, record should
be made of the removal and return

Location and Furnishings

The hospital medical library should occupy a prominent location, preferably in the hospital building. The actual location of the room will affect directly the amount of usage. If it is placed in an obscure corner of a floor that is used very little as compared with other floors, it will naturally not be visited often.

The location should be chosen with a view to attractiveness, convenience and comfort to those who will use the library. It is often preferable to have it on the administrative floor or in close proximity to the doctors' room.

The room should be sufficiently large to house the books along with the necessary furnishings, and to permit its comfortable use for reading, discussion and conversation. The very atmosphere of the room will have much to do with the extent to which the library will be used.

It would be worth while for those interested in developing such a library to visit similar libraries and study the elements that seem to make them a success. Any well ordered and well used library, whether medical or not, would furnish good suggestions. The best type of shelf or rack is whatever enables the book or journal to be quickly found, easily removed and easily replaced. There should be a complete card index. Binding journals into volumes adds to their life and usefulness.

Reading Matter

In establishing the library, it is well to purchase only one or two comprehensive textbooks on each subject. Only recent books should be chosen, with the exception of such standard works as are recognized as classics in their respective lines, and which do not grow obsolete with age. The literature on therapy and diagnosis, for example, is changing so rapidly as to warrant the use of the most recent books. In the field of the more fully developed sciences, such as anatomy and histology, literature is more stabilized and longer lived. More recent editions of the standard textbooks should be added from time to time, thus keeping the library up to date with regard to new methods of diagnosis and treatment that have been digested and tested. After a good foundation has been formed, the balance of the apportioned funds may be expended in purchasing varied references that are known to be of particular value. The library should not be allowed to become a depository for antiques, and out of date books should be removed or discarded.

The usefulness and efficiency of the hospital medical library depend not only on a good selection of medical books but also on a well chosen group of periodicals. Limited library funds are often more usefully expended for periodicals than for texts and references. When ample funds are provided there is no great difficulty experienced in the matter of choice.

The hospital medical library may supplement its service by the use of state medical school libraries, county society libraries (in some cases), and the package library of the American Medical Association. The package library consists of collections of reprints and other material on various subjects, prepared for lending to members of the Association and to individual subscribers to publications of the American Medical Association. Information on the loan systems of state medical school libraries or society libraries can readily be obtained on inquiry.

Dr. Vincent¹ at the fiftieth anniversary of the Boston Medical Library in 1926, spoke of the library as being part of the social memory.

"A medical group which works with little or no reference to books and journals suffers serious limitations. Without knowledge of what others have discovered, daily experience cannot be resourcefully interpreted. Avoidable mistakes, waste and duplication of effort are inevitable. Doctors become victims of empiricism and routine, imagination and initiative lack stimulus, enthusiasm and energy decline, minds grow sterile that under the quickening influence of the recorded experience of others might have been fruitful."

Harvey Cushing,² in his address at the opening of the new building of the Cleveland Medical Library in 1926, aptly states

¹ Boston Medical Library. Celebration of the fiftieth anniversary Jan. 19 1926. Boston 1926.
² Cushing, Harvey. The Doctor and His Books. Cleveland 1926.

"The soul of an institution that has any pretense to learning comes to reside in its library, and no less well may one gauge the quality of a medical school, of a hospital, of a laboratory, of the individual doctor himself, than by the condition of its library."

SUGGESTED PERIODICALS

A selection of a few leading medical journals is indispensable. Obviously, the average hospital library will contain only a portion of the following list. It is desirable that the library of a general hospital should select its periodicals from those included under "Medicine" and "Surgery" before journals from the special lists are made available. The specialties receive a certain amount of attention in the general medical and surgical publications listed below.

A Diabetic Manual for the Mutual Use of Doctor and Patient By Elliott P Joslin MD Clinical Professor of Medicine Harvard Medical School Fifth edition Cloth Price \$2 Pp 224 with 50 Illustrations Philadelphia Lea & Febiger 1934

This edition of Joslin's diabetic manual for the mutual use of doctor and patient is thoroughly revised and constitutes a valuable form of this standard textbook. It is packed full of useful information, encouragement for the patient with diabetes, and warnings against carelessness. It is a complete answer to the doubts and fears of wavering diabetic patients who grow tired of diet and insulin and are tempted to follow the will o the wisps of quackery to their own speedy destruction. Joslin characterizes the diabetic patient as "his own nurse, doctor's assistant and chemist" but immediately warns that "if he tries to be his own doctor he will come to grief." Of particular interest is the incontrovertible evidence Dr Joslin presents that diabetes has become more and more a disease of old age. The death rate is decreasing among all the age groups except those past 50. Especially hopeful is the outlook for diabetic children, this, of course, is in sharp contrast to the situation before insulin was introduced in 1922. The author is uncompromising in his statements that a properly advised patient can control his diabetes. He designates the following ingredients as essential in the treatment of diabetes: medical supervision, cooperation of the patient, diet, exercise, insulin, brains and character. Even persons who do not have diabetes would make no mistake in reading this book because of the emphasis on prevention of diabetes through weight control, avoidance of marriage among individuals with diabetic family histories, and general supervision of the dietary.

Intercortical Systems of the Human Cerebrum Mapped by Means of New Anatomical Methods By Joshua Rosett Assistant Professor of Neurology Columbia University Cloth Price \$3 Pp 133 with 41 Illustrations New York Columbia University Press 1933

The fibers in the white center of the cerebrum are arranged in parallel rows to form flat bands and sometimes lamellae of paper-like thinness. In many places these lamellae lie one on another and can be dissected away one at a time like the layers of an onion. This is particularly true of the association fibers joining different parts of the cerebral cortex. These lamellae and the arrangement of their constituent fibers have been studied in detail by Rosett. For this investigation he used a new method, charging the brain with carbon dioxide under pressure of about 1,000 pounds and then allowing it to explode, thus rendering conspicuous the planes of cleavage between the lamellae. Since the pictures thus obtained are quite fragmentary and the observations that Rosett has made have not been combined into a comprehensive account of the association pathways of the cerebral hemisphere, the book will be of interest chiefly to those who are concerned with the minutiae of the intercortical fiber systems.

Allen's Commercial Organic Analysis A Treatise on the Properties Modes of Analysis and Proximate Analytical Examination of the Various Organic Chemicals and Products Employed in the Arts Manufactures Medicine Etc With Concise Methods for the Detection and Estimation of Their Impurities Adulterations and Products of Decomposition Volume X Haemoglobin and Its Derivatives Albuminoids or Scleroproteins Structural Proteins Examination of Foodstuffs for Vitamins The Hormones The Identification of Unknown Woods and Charcoals The Pectic Substances Edited by C Alsworth Mitchell MA DSc FIC Consulting Chemist London (General Reference Index by M B Elliott) Fifth edition Cloth Price \$7 50 per volume Pp 317 with Illustrations Philadelphia P Blakiston's Son & Company Inc 1933

This volume, the tenth of this important series, completes the fifth edition. It contains monographs by various writers on hemoglobin and its derivatives, albuminoids, structural proteins, vitamins, hormones, identification of woods and charcoals, and pectic substances. These maintain the standard of the earlier contributions to this work. A general index to the whole ten volumes completes the book. The section on hemoglobin by Gardner and Buckmaster contains much valuable information but does not attain the completeness expected in a reference series of this sort. It is surprising to find that the only devices described for estimating erythrocytes are the antiquated Gower and Thoma-Zeiss hemacytometers, that diameters of blood cells are given in some tables in fractions

of an inch without the equivalent metric dimensions, that blood grouping is stated only according to the classification of Moss (although it is not here attributed to Moss and no mention is made of the widely used Jansky method or of the Landsteiner classification, which is supplanting both), that the Van Slyke method for hemoglobin is not mentioned. The monograph by Jerome Alexander on albuminoids is unusually complete, that on structural proteins by R. H. Marriot includes much valuable material. The succeeding section on vitamins, by Drummond and Coward, contains adequate data for assay, together with an appendix on the international standards, but, as admitted by the authors, it is unfortunately not up to date. The hormones are considered by Culhane and Underhill, their work is useful for reference, but several of the important newer methods and tests are not included. Although, for instance, the Allen-Dorsey method for assay of estrogenic substance is discussed one looks in vain for the Aschheim-Zondek pregnancy test. The methods of making suprarenal-cortical extracts proposed by Swingle and by Hartman are described, but the earlier and more satisfactory method of Rogoff is not given. The volume is completed by valuable sections on woods by J. Cecil Maby and on pectic substances by H. W. Buston.

Pediatric Nursing including the Nursing Care of the Well Infant and Child. By Gladys Sellev, M. A., B. S., R. N., Director Nursing Education, Chicago City Infant Hospital Affiliated with De Paul University. Third edition. Cloth Price \$2.50. Pp. 609 with 53 illustrations. Philadelphia: London: W. B. Saunders Company, 1933.

This edition explains and applies the newer developments in pediatrics and pediatric nursing. The changes in the section on communicable diseases are especially emphasized. There is a new section detailing the organization and special nursing procedures required in the Children's Clinic. Each chapter is now concluded with a series of questions for quiz work. This textbook is designed especially to help the student nurse to understand both well and sick children. Portions are devoted to practical considerations in caring for the normal child from birth on, and then sections to pediatric nursing, i. e., nursing procedures involved in routine ward work, procedures connected with the admission of the child to the hospital, and other procedures. Following these, the medical aspects of children's diseases are presented with detailed directions on the nursing care of every pediatric condition, including orthopedic nursing. Emphasis is placed on mental hygiene and development. A list of books for children of various ages on various subjects is appended. It is logical that a nurse is not qualified to discuss the medical aspects of diseases and infant feeding without the assistance of a physician. Realizing this Miss Sellev has had many of the portions of the book dealing with the description of diseases and infant feeding written by a qualified physician. It is a highly satisfactory book on pediatric nursing.

New Introductory Lectures on Psychoanalysis. By Sigmund Freud, M.D., LL.D. Translated by W. J. H. Sprott. Cloth Price \$3. Pp. 257. New York: W. W. Norton & Company, Inc., 1933.

Freud's first series of introductory lectures appeared in 1916. The present volume is a new work, constituting a series of lectures published in Vienna in 1933. The seven lectures cover a revision of the theory of dreams, dreams and the occult, the anatomy of the mental personality, anxiety and instinctual life, the psychology of women, orientations and a philosophy of life.

The chapter on the psychology of women presents the point of view that woman is a passive element, that her aggressiveness is constantly repressed and that the riddle of femininity will not be solved until there can be understanding of the differentiation of living creatures into two sexes. The author makes much of the point of view that the girl and woman constantly seeks development of those organs and tissues that will give her the position of the male.

Most interesting of all is, of course, the philosophy of life of a man who has devoted all his life to a better understanding of others. The author says: "At a time when great nations are declaring that they expect to find their salvation solely from a steadfast adherence to Christian piety the upheaval in Russia—in spite of all its distressing features—seems to bring a promise of a better future. Unfortunately, neither our own misgivings nor the fanatical belief of the other side give us any hint of how the experiment will turn out. The future will

teach us. Perhaps it will show that the attempt has been made prematurely and that a fundamental alteration of the social order will have little hope of success until new discoveries are made that will increase our control over the forces of nature and so make easier the satisfaction of our needs. It may be that only then will it be possible for a new order of society to emerge which will not only banish the material want of the masses but at the same time meet the cultural requirements of individual men. But even so we shall still have to struggle for an indefinite length of time with the difficulties which the intractable nature of man puts in the way of every kind of social community."

Thomas Young, F.R.S., Philosopher and Physician. By Frank Oldham, M.A., B.Sc., A.Inst.P. Cloth Price \$2.40. 1 p. 1-9 with 16 illustrations. New York: Longmans, Green & Company; London: Edward Arnold & Company, 1933.

An infant prodigy, born in England in 1773 of Quaker parentage, Thomas Young became an interesting contributor to many branches of medical science. He could read at the age of 2 and knew the "Deserted Village" by heart before he was 6. He burned with a thirst for learning and equipped himself to participate in the advancement of many branches of science. After a medical education in London and in Edinburgh he extended his studies in Germany, and there are numerous quotations from his writings depicting the young man's appreciation of life and learning in these places. In order to receive a medical degree he returned to Cambridge and took two years there graduating in 1797. After his graduation he inherited a fortune of £10,000, so that he was able to devote himself to medical practice, but perhaps by the very reason of his fortune he failed to develop a good bedside manner and thereby made little success as a popular physician. His fame in medicine rests on his work as a compiler, historian and publicist. He wrote an introduction to medical literature and an essay on consumptive diseases. He was, however, particularly interested in natural philosophy. His contributions in medicine include studies of sound and light, the establishment of the undulatory theory of light, studies of the mechanisms of the eye and of capillarity, and finally researches in Egyptian hieroglyphics. His translation of the second portion of the Rosetta stone was a notable performance. It is said of him that he was the first to grasp the idea of a phonetic principle in reading Egyptian hieroglyphics.

Children of Preschool Age. Studies in Socio-Economic Status, Social Adjustment and Mental Ability with Illustrative Cases. By Ethel Kewin, Research Psychologist, Behavior Research Fund and Institute for Juvenile Research. Cloth Price \$3.50. Pp. 340 with illustrations. Chicago: University of Chicago Press, 1933.

The exact value of this book is difficult to determine. It is a report of some of the work of the preschool department of the Illinois Institute for Juvenile Research. Only a few conclusions are presented. The mass of the material is taken up with case presentation, which at times is dull lengthy and accompanied by extraneous statements. Probably the most important conclusion that could be found in the book is that the constancy of the Merrill-Palmer scale remains an open question and that possibly the scale will be found more reliable on extensive study than it appears to be from the data in this study. Other conclusions are drawn, such as that there are a group of factors which appear to be related to the child's social adjustment, a conclusion that does not need substantiation by a large mass of research. If the book should be greatly shortened, its value might be increased.

Heredity and the Social Problem Group. By E. J. Liddbetter. Volume 1. Cloth Price \$7.50. Pp. 160 with illustrations. London: Edward Arnold & Company; New York: Longmans, Green & Co., 1933.

This volume includes essentially a series of family charts and pedigrees for families in which mental defect is apparently associated with poverty and the fact that the family becomes a charge on the community. Each of the pedigrees is supplemented by a brief analysis. The charts bring out the striking fact that families in which mental defects appear tend to intermarry. The exhibit is an impressive demonstration of the necessity for some sort of social control in order to prevent undue propagation of the unfit.

Contagious Diseases What They Are and How to Deal with Them By W W Bauer B.S. M.D. Director Bureau of Health and Public Instruction American Medical Association Cloth Price \$2 Pp 218 New York Alfred A Knopf 1934

In this volume Dr W W Bauer director of the Bureau of Health and Public Instruction of the American Medical Association, has assembled a series of articles, on the infectious diseases, many of them printed in *Hygiene*. The essential facts for every family that wants to be well informed are here provided in easily readable form. The material is up to date and intensely practical. Physicians may recommend this book without question to any family interested in the facts regarding the conditions commonly appearing among children. It has long since been recognized that intelligent lay cooperation with the medical profession is desirable for better control of infectious diseases. The purpose of this little book is to improve such cooperation.

A Text Book of Physiology for Medical Students and Physicians By William H Howell Ph.D. M.D. Sc.D. Twelfth edition Cloth Price \$7 Pp 1132 with 308 illustrations Philadelphia & London W B Saunders Company 1933

Because of the advance in our knowledge of the vitamins the hormones and the chemistry of muscle contraction the twelfth edition of this standard textbook of physiology first introduced in 1905 has been revised, reprinted and recopyrighted. The author has brought his book quite up to date and has presented a number of historical introductions to the discussions of some of the topics in order to give the student a proper perspective on the manner in which science advances. This textbook is one of the most widely used by American teachers of physiology.

The Great Doctors A Biographical History of Medicine By Dr Henry E Sigerist Professor of the History of Medicine the Johns Hopkins University Translated by Eden and Cedar Paul Cloth Price \$4 Pp 436 with illustrations New York W W Norton & Company Inc 1933

This volume, translated from the German offers a biographic approach to the history of medicine. It includes biographies of from eight to twenty pages each of epoch makers from the time of Hippocrates to that of William Osler. The literary style of Dr Sigerist his philosophical approach to his subject and his comprehensive grasp of medical affairs make the book of interest not only to the physician but also to the general reader. It is interesting to find in Dr Sigerist's sketch of William Osler his personal appreciation of Osler's humanism and Osler's deprecation of a fixed program for medicine.

A Text Book of Medicine By American Authors Edited by Russell L Cecil A.B. M.D. Sc.D. Professor of Clinical Medicine Cornell University Medical College Associate Editor for Diseases of the Nervous System Foster Kennedy M.D. F.R.S.E. Professor of Neurology Cornell University Medical College Third edition Cloth Price \$9 Pp 1664 with 30 illustrations Philadelphia & London W B Saunders Company 1933

Here is a one volume system of medicine in its third edition, the last one having appeared some three years ago. In that period of time as is pointed out in the preface there have been additions to our knowledge, particularly in the field of infectious diseases and of endocrinology. New articles have been added on many of the rarer infectious diseases, and some of the older articles have been rewritten by new contributors. Because of the numerous changes the publishers have reset the entire work, which incidentally shows the effects of repeated competent revision. The volume is one of the best available to the practitioner who wishes a succinct textbook of the practice of medicine.

Le poison des amanites mortelles Par B Dujarric de la Rivière Paper Price 60 francs Pp 182 with 24 illustrations Paris Masson & Cie 1933

This monograph on the most important group of poisonous mushrooms the deadly Amanitas is clearly written and well illustrated. There is a bibliography of twenty eight pages and also a list of pertinent articles and brief notes appearing in the *Bulletin de la société mycologique de France* from 1885 to 1931. The index is quite inadequate. The monograph discusses the botanic classification of the Amanitas the chemistry and physiologic action of the poison the gross and histologic lesions caused in man and laboratory animals scrotherapy medicolegal

considerations and prophylaxis. The author's own researches are included and the book is a real addition to the literature of mushroom poisoning. It is too bad that French writers and publishers do not pay more attention to the correct transcribing of quotations in English, English and American proper names and the titles of English and American periodicals.

Giants and Dwarfs A Study of the Anterior Lobe of the Hypophysis By Palmer Howard Fletcher Boards Price \$1.25 Pp 80 with 3 illustrations Cambridge Mass Harvard University Press 1933

This is an honors thesis in science of the class of 1932 at Harvard. It constitutes an adequate survey of our knowledge of the relationship of the pituitary gland to disturbances of growth. The book is nicely written and handsomely published.

Health Facts for College Students A Text Book of Individual and Community Health By Maude Lee Etheredge M.D. Dr.P.H. Professor of Hygiene and Medical Advisor for Women University of Illinois With a foreword by Ray Lyman Wilbur M.D. Cloth Price \$2 Pp 342 with 61 illustrations Philadelphia & London W B Saunders Company 1933

This book consists of the material formerly used in mimeographed form for the classes of women students at the University of Illinois. It is essentially a compilation in rather popular form of the well established facts of personal hygiene. The volume is a reliable guide to the minimum of knowledge that every college graduate ought to have on the care of the health and the leading of a hygienic life.

Voluntary Motherhood A Discussion of the Various Contraceptive Methods with Emphasis on Generally Approved Techniques By Antoinette F Konikow M.D. Fourth edition Paper Price 50 cents Pp 36 with 8 illustrations Boston Buchholz Publishing Company 1933

This pamphlet, now in its fourth edition, promotes the use of the intravaginal rubber pessary associated with antiseptic pastes and douches as the ideal method for widespread birth control. There are, however, innumerable physicians who are convinced that this method, strongly supported by the Margaret Sanger group, is unsatisfactory from the esthetic point of view as well as from the medical point of view.

Industrial Health Service By Leverett Dale Bristol M.D. Dr.P.H. Health Director American Telephone and Telegraph Company New York New York Cloth Price \$2 Pp 170 Philadelphia Lea & Febiger 1933

The author is health director of the American Telephone and Telegraph Company. He divides his book into sections depending on the use of the health service from the point of view of the management the supervisor and the worker. It is an exceedingly practical manual but so condensed as to offer little of importance to the experienced worker in this field.

Some Modern Extensions of Beaumont's Studies on Alexis St Martin By W B Cannon M.D. Sc.D. LL.D. George Higginson Professor of Physiology Harvard Medical School Beaumont Foundation Lectures Twelfth Series Reprinted from the Journal of the Michigan State Medical Society March May 1933 Cloth Pp 87 Detroit Lectureship Foundation Committee Wayne County Medical Society 1933

This is a reprint from the *Journal of the Michigan State Medical Society* of a series of lectures given by Dr W B Cannon to commemorate the one-hundredth anniversary of the publication of Beaumont's essay on digestion. These lectures deal with thirst and hunger the important relation of digestion and health, and digestive disturbances produced by pain and emotional excitement.

Lectures on the History of Medicine A Series of Lectures at the Mayo Foundation and the Universities of Minnesota Wisconsin Iowa North western and the Des Moines Academy of Medicine 1926 1932 Cloth Price \$5 Pp 516 with 26 illustrations Philadelphia & London W B Saunders Company 1933

The essays herein contained were given from 1926 to 1932 through a cooperative arrangement between the Mayo Foundation and a number of midwestern universities. The collection embraces contributions by many leading medical historians as well as some by practitioners with whom the history of medicine has been a hobby. All the essays will be appreciated by those interested in medical history. They reveal as is invariably the case an unevenness of literary quality and an unevenness of approach. Some of the essays represent condensations of longer works by the authors on the same subject. Of special

interest are the four contributions by Fielding H Garrison, the essay on the first American medical journals and Dr Willard Bartlett's sketch of the life and time of Virchow, a figure whose contribution to the advancement of medicine is almost always underestimated

Medicolegal

Narcotics Sale of Cigarets by Dealers in Narcotics Prohibited—The city of Reno passed an ordinance prohibiting the sale of cigarettes in any place of business where narcotic or poisonous drugs are kept for sale. A preamble to the ordinance set forth that cigarettes containing narcotic and poisonous drugs were being sold in Reno and that the handling of cigarettes in places where such drugs are dispensed makes readily possible the addition of them to cigarettes and thereby endangers the health, comfort, safety, life and welfare of the inhabitants of the city. Nash, the manager of a drug store, was charged in the justice's court in Reno with a violation of the ordinance. He was arrested and thereupon filed in the Supreme Court of Nevada a petition for a writ of habeas corpus, contending that the ordinance was unconstitutional. That a city ordinance or police regulation, said the Supreme Court, forbids acts theretofore innocent and lawful affords no ground for holding such legislation either void or unreasonable. The foundation for this ordinance was the sale and distribution in Reno of cigarettes containing narcotic and poisonous drugs. Assuming this to be a fact, reasonable legislation to suppress such a publicly notorious evil cannot be overthrown on the ground that it is arbitrary and capricious. The constitution does not limit the exercise of the police power to suppress and prevent the use of cigarettes or any article of trade as agencies to facilitate the sale and use of dangerous and habit-forming drugs.

The court could find no principle in the federal or state constitution violated by the enactment of the ordinance. It therefore ordered the writ of habeas corpus discharged and Nash remanded to the custody of the chief of police of the city of Reno.—*En route Nash (Nev)*, 26 P (2d) 353

Workmen's Compensation Acts Aggravation of Injury by Malpractice of Employer's Physician and Nurses Compensable—A particle of concrete became embedded in an employee's eye in the course of his employment. The employer's physician and nurses treated him in first aid rooms maintained by the employer, but he lost his eye. Instead of claiming compensation under the workmen's compensation act he brought an action at law against his employer. He contended that the loss of his eye was due to malpractice by the physician and nurses who treated him and that there was no causal relation between the industrial accident and the loss of his eye. Therefore, he argued, the injury from which he suffered was an independent injury for which he was entitled to recover damages in an action at law. The supreme court of New Jersey allowed the case to go to the jury on the theory that the injury, due to malpractice, was independent of the original injury, which arose out of and in the course of employment. Judgment was given in favor of the employee. The employer appealed to the Court of Errors and Appeals of New Jersey.

The employee, in the opinion of the Court of Errors and Appeals, could not recover damages from his employer in an action at law, even though the injury complained of did not arise out of and in the course of his employment and did not come within the purview of the workmen's compensation act. An employer is liable at common law, for the malpractice of a physician or nurse employed by him to treat or care for his employee, only if he has not used reasonable care in selecting that physician or nurse. In the present case nothing in the record shows that the defendant-employer was negligent in that respect.

But, in the opinion of the court, the injury complained of did arise out of and in the course of the plaintiff's employment, and therefore the workmen's compensation act furnished the only remedy. If a physician furnished by an employer is guilty of malpractice in treating an industrial injury, under the work-

men's compensation act the employer is liable, for there is a causal relation between the employment, the industrial accident and the injury. In the present case, without the employment there would have been no accident, without the accident there would have been no treatment of the plaintiff's eye by the defendant's physician and nurses, without such treatment the eye would not have been lost.

The court held therefore that the plaintiff employee should have proceeded under the workmen's compensation act and not at law, and entered judgment in favor of the employer.—*Tutino v Ford Motor Co (N J)*, 168 A 749

SOCIETY FOR THE PREVENTION OF
ASPHYXIAL DEATH*Second Annual Conference held in New York Feb 19 20 1934*

The President, PALUEL J FLAGG, M D, New York, in the Chair

How Antiquity and Medieval Europe Looked upon
the Problems of Asphyxiation

DR JAMES J WALSH, New York. Hippocrates suggested that in inflammatory croup with difficulty of respiration a cannula should be carried into the throat so that the air could be drawn into the lungs past the obstruction. The use of the cannula or tube for the relief of asphyxiation is next heard of among a group of French surgeons during the first quarter of the nineteenth century. Early in the century Desault succeeded in placing a tube in the larynx apparently, restoring respiration and lengthening patients' lives. About 1820 Patisier, another French surgeon, suggested that some such mechanical procedure should be employed for edema of the glottis.

In spite of this interest in the procedure for intubation the practice died out, and it seemed to be a closed chapter in medicine and surgery. Here in New York, Dr Joseph O'Dwyer as attending physician to the Foundling Asylum had to witness a number of deaths from asphyxiation. He resolved to relieve these cases by mechanical means. It required a great deal of experiment to determine what sort of tube could be inserted without much difficulty and would be retained, but O'Dwyer gradually worked it out and proceeded to save a great many lives among the children and nurses at the Foundling Asylum.

O'Dwyer then read a paper before the New York Academy of Medicine in which he described his success with intubation. The pediatricians told him that intubation had been tried by the Greeks and given up and then had been studied by the French, who found it of no value. O'Dwyer took these specialists to the Foundling Asylum to show them what he was doing there. No doubt of his success was left in their minds.

Dr Trousseau, the distinguished French clinician about the middle of the nineteenth century reintroduced tracheotomy and in many cases of blocking of the rima glottidis this procedure afforded relief, but in diphtheria very few recovered. O'Dwyer said that he had been aroused to experimentation in this direction by the complete failure of tracheotomy for some ten years at the New York Foundling Asylum. As regards the early operations for tracheotomy, Colonel Garrison whom I consulted, suggests that there is the probability that prehistoric man may have slit open the gullet of a person suffocating from croup or diphtheria. The first successful case of tracheotomy in modern times, is the operation performed during the course of diphtheria by Bretonneau on Elizabeth de Puysegur, July 1, 1825. After five failures he succeeded in opening the trachea and affording relief. Trousseau was the first Parisian clinician to perform tracheotomy for diphtheria and his operation was done on Gustave de Marcelet, Nov 23, 1831.

Dr Joseph O'Dwyer—Pioneer in the Prevention of
Asphyxial Death

DR HENRY HALL FORBES, New York. Joseph O'Dwyer, the inventor of the O'Dwyer intubation tube and later of an instrument for artificial respiration, was my teacher. I served under him as an intern at the New York Foundling Hospital in 1892-1893, while he was perfecting his intubation tubes for the relief of children suffocating from laryngeal diphtheria. Dr O'Dwyer had in mind also the invention of an instrument to use in cases of asphyxia from other causes. The instrument was inserted into the larynx and held there. The rubber tube went to a foot pump on the floor. With the thumb covering the opening, and with gentle pressure the respiratory rate was maintained at the rate of from 18 to 20 movements to the minute.

Dr O'Dwyer had quite a general practice in addition to his specialty in children. He was a native American and his early training was in the office of a physician. In 1866 he was graduated from the College of Physicians and Surgeons. After graduation he served on the staff of the Charity Hospital. He passed through two epidemics of cholera, which he contracted

twice. In 1872 he was appointed to the staff of the New York Foundling Hospital. In those days a diphtheria epidemic there would have a mortality rate of from 40 to 50 per cent. I used to go over to the contagious building at the Foundling Hospital and see children grasping the sides of the crib, breathing that way, blue and suffering. After a tube had been inserted they would lie down and go to sleep. How many lives were saved is uncertain. In 1887 Dr O'Dwyer appeared in the autopsy room with a new tube adopted to fit the larynx and not easily coughed out. A search through the records of the New York Foundling Hospital reveals that Dr O'Dwyer first applied his "spring tube" in relieving severe dyspnea of a child suffering from diphtheria, Oct 24 1882. April 23, 1884, he first applied the "oval tube" in a baby of 3 months suffering from dyspnea caused by diphtheritic laryngitis. Dr O'Dwyer's first public presentation of his method appeared in the *New York Medical Journal* in 1885 under the title "Intubation of the Larynx." In 1892 before the American Pediatric Society he gave a talk on an improved method for performing artificial respiration. He refused to take much of the credit and described his apparatus as a modification of the method devised by Dr George E. Fell of Buffalo. In 1894 he was invited to talk before the British Medical Society. He urged Dr Northrup to make the trip and in three days Dr Northrup was on the high seas. The paper presented at that gathering was published in the *British Medical Journal* for that year.

For years Dr O'Dwyer was lecturing on intubation and allied problems at the Bellevue Hospital Medical College and at the Post-Graduate Hospital, yet he found time to take the presidency of the American Pediatric Society. He died, Jan 7 1898, of a brain condition at his home in New York, aged 57.

Differential Pressures in Resuscitation
and Thoracic Surgery

DR POL N CORYLLOS, New York. Anoxemia and acapnia are the two causes of asphyxial death. The importance of carbon dioxide should not be underestimated. No rational treatment of anoxemia can be carried on without an exact knowledge of the significance of carbon dioxide in respiration. In the diagnosis of asphyxia the presence of cyanosis is not compulsory. On the contrary, the most dangerous forms of anoxemia are accompanied by excessive elimination of carbon dioxide and consequently by absence of cyanosis. In these cases death occurs without any conspicuous symptoms. In thoracic surgery, the anesthetist is one of the most important members of the surgical group. The treatment of respiratory disturbances must be carried out by specially trained men. It is hoped that this work will be carried on in the future by the anesthetist, who, more than any one else is prepared for this task.

(The author showed a film representing the experimental production of atelectasis and measurement of gas changes behind the obstructed bronchus in the alveoli in an experiment carried on in the Cornell Medical College Surgical Research Laboratory in connection with Dr Birnbaum.)

The Problem of Electric Shock

DR HORATIO B WILLIAMS, New York. The first large industrial application of electricity was in the lighting of cities with carbon arc lamps, which took about 45 volts apiece. About 1880, I think, Edison introduced the carbon filament incandescent lamp, which was originally operated on 110 volts direct current. Later came the introduction of extended power circuits. It is impossible to transmit 110 volts direct current economically over any great distance. But alternating current can be transmitted at high tension. With the coming of the alternating current and high tension up to maybe 100,000 volts, when people got across those high voltages not only was the skin burned but sometimes the body was practically incinerated. The bones may be melted. It isn't an asphyxial death when the current kills by heating effects. If there is a good contact from the head to the feet enough heat may be generated in the head to throw the eyes out of the sockets.

There is another type of death by electricity. In the last fifteen years there have been reports about people who seem to die from touching low voltage alternating current circuits. At first nobody believed it. The whole thing is simple. For a 110 volt circuit to kill it is necessary that the skin be suffi-

ciently moist, that the contact be sufficiently large, and that the current pass through the chest in sufficient quantity to throw the ventricles into fibrillation. Not every case of ventricular fibrillation continues to death, but the usual outcome is death. In case of electric shock, artificial respiration will often maintain a sufficient circulation to keep the cellular elements of the central nervous system alive.

Alternating current, which is much more dangerous than direct current, is almost universal now. Numerous deaths from low voltage electric shock have occurred when people are in the act of taking baths. A typical accident happened on a day when there was a thunderstorm. It got dark. When a man got ready to dry himself after bathing, he reached to pull the chain. The wire in contact with the outside of the fixture was the wire that didn't connect to the ground, the other wire being connected with the ground. Standing in the bathtub, he made a connection with his wet hands from the outside of the fixture down to his body and got enough shock to the heart to start fibrillation. Artificial respiration is the treatment. It should be long continued. One never can tell how late it may be possible to resuscitate the patient. Another way to get hurt is in a laundry. Electric washing machines ought to be safe. They are when they come from the manufacturer. In the laundry the floor may be wet. The operator gets his hands in the water and gets them good and wet. The contact is on the live side and the damage is done.

All this suggests that designers should have their attention drawn to the necessity of taking particular care of appliances that are used in kitchens, laundries, laboratories, bathrooms, chemical factories, damp cellars, places where people sweat and where the body gets wet, and that the public should know there may be danger. In domestic establishments if grounding of either side of the circuit could be avoided one couldn't get a shock unless one came in contact with two wires. There are many ways to get in contact with one wire in the ground. The number of people killed in New York City by motor accidents vastly exceeds the number of people killed by shock on low voltage circuits all over the world. That is no reason why this matter should be neglected. It is a great deal easier to prevent these deaths than it is to prevent the motor deaths.

DISCUSSION

DR C. H. WATSON, New York. In the Bell System about 80,000 men are trained in first aid. The work has been carried on for about twelve years on this scale. I believe that, in the individual who has been in contact with electric energy and is apparently dead, the heart phenomena constitute the most important thing that is taking place. The heart has gone into a period known as ventricular fibrillation. For that reason, various ways of artificially pumping blood have been provided. I believe that the Schafer method provides the easier administration of the mechanical pressures necessary to force blood through an individual's body, while the fibrillating heart is just churning and not sending it out into the peripheral circulation. In the last year in the Bell System 8,000 men have been working on all kinds of wiring articles. There have been six instances of electric shock, and only one of them resulted fatally. Until some other device is more easily handled and more cheaply obtained, the Schafer method of artificial respiration should continue to be taught.

DR HORATIO B. WILLIAMS, New York. There is a treatment for ventricular fibrillation but at present it is not applicable to cases in the field. It consists in countershock applied to the heart. In the laboratory it will succeed in a good many cases. If the equipment was available and the personnel of the plant could be trained properly they might be able to make a resuscitation with it. On the other hand one has to know for sure that one is dealing with the fibrillation before one applies countershock, which in itself is not the safest thing in the world. I may say by way of encouragement that in experimenting on animals I find there is a tendency for the fibrillation to stop in the smaller animals after a sufficient length of time, if the heart and other structures are kept alive. It may happen in an accidental case even though it is a rather rare occurrence. But it always pays to keep up artificial respiration until the last minute. I particularly like the Schäfer method because of the fact that in doing it one massages the heart and helps to keep the circulation going.

The Problem of Submersion

DR CHARLES NORRIS, New York. Drowning is an asphyxial death. It is only essential that sufficient water be present to cover the nostrils and mouth. Sidney Smith states that a person falling into the water sinks immediately after the fall and with the force of gravity breathing stops immediately. Deaths occur from shock or injury or heart failure due to heart lesions or inhibitions. Usually the person rises to the surface, owing to the natural buoyancy of the body and tries to save himself. Violent attempts are made at reaching the surface, and if the head is under water a certain amount of water is inhaled and thus the dyspnea is increased. A person strikes cold water and swallows a certain amount of water, and some of this water reaches the laryngeal mucous membrane. This is really the first stage of drowning. It is known by the name of "respiration de surprise." Inhibition of respiration ensues. In other words, a person may die in water and if respiration does not start again he will not inhale water. Although he dies from asphyxia his body will not present the picture of a typical drowning case. When a person drowns in salt water and inhales a considerable amount of salt water, the blood of the left side of the heart on account of the absorption through the air vesicles, will be increased as to its salt content, for the reason that salt water contains more sodium chloride than does the blood.

Drowning in fresh water is the opposite. There will be less sodium chloride in the left side of the heart than in the right. The chemist who is not informed by the pathologist will report that the death is not due to drowning because there is no essential difference in chloride content of the left and right sides of the heart. This is, of course, a grievous error. There are also a number of instances in literature in fairly well proved cases in which perforated ear drums have caused syncope and the people naturally drowned, being in the water. The postmortem signs in the recently drowned are pronounced and they offer no difficulty in determination. The convulsive movements that occur in the stage of terminal asphyxia in which the automatic respiratory efforts cause water to be drawn into the bronchi and cause air to be drawn into the air vesicles constitute the stage that produces the characteristic ballooning in the lungs. The extent of ballooning of the lungs depends on the duration of the terminal stage and the extent of postmortem signs, which will vary with the struggle.

As in almost all asphyxial deaths the heart does not stop beating immediately, especially the right auricle which may continue to beat after respiration has ceased. This is known as the "ultimum moriens Halleri." The beating of the heart is favorable to attempts at resuscitation, and if this is not delayed too long will be successful. If delayed serious changes in nerve matter around respiratory vesicles will have occurred. One cannot determine on external inspection alone that a body has died from drowning. The characteristic foam at the nose is not typical of drowning, as it is present in all cases of pulmonary edema.

In 1932 the number of submersions in New York City was 377. An important sign of drowning is the presence of water in the stomach. It is characteristic of drowning, but it may be concealed when a person has been drinking before the accident or if the deceased has had a very large meal. In many cases the water extends into the duodenum. I have usually found an absence of fluid in the duodenum or small intestine. I do not know the reason for this. A dead person thrown into the river will not show signs of drowning. Deaths in water from natural causes are at times difficult of determination. When the death is due to laryngeal inhibition similar to the sudden deaths due to the choking of the larynx with a piece of meat or other foreign obstacle the determination may be of great difficulty and may be really undetermined unless the surrounding circumstances are ascertainable, through witnesses to give a clue.

DISCUSSION

DR HOWARD W. NEAL, New York. Two recent cases of drowning emphasize the importance of laboratory technique. Some children were playing in an excavation that had been made for a cellar many miles from the ocean. When the blood from both sides of the child's heart, who had broken through the ice and drowned was sent to the laboratory it was found that the left side contained 548.8 mg of sodium chloride per hundred

cubic centimeters and the right side of the heart 509.6, making a difference of 38.9. It was thought that the child had drowned in fresh water, but further investigation revealed that a grocer had emptied a barrel of salt brine a block away from the cellar on the side of a hull and perhaps the salt had been washed down by rains in the water.

MR ROBERT P. MACFADDEN, New York. The Volunteer Life Saving Corps received a charter in the state of New York in 1890. The purpose of this corps was to establish life-saving stations along the waterfronts of Greater New York, patrol the waterfront and protect the lives of people who happened to get into the water. The corps has sixty-two stations in Greater New York. There are 10,000 members of the corps of which about 5,000 are active at present. During 1932 there were 500 rescues involving the use of resuscitation. Assistance was rendered in 800 cases not necessitating resuscitation. There were about 8,000 first-aid cases. There are no paid members of the corps at present, the work being regarded as a hobby. During 1932 the volunteers gave to New York City 35,000 days' work which is quite a saving to the city. A good many other departments in the city sometimes take the credit or receive the credit for the work.

DR P. N. CORALLOS, New York. There are three periods in drowning. The first is the period of apnea during which the blood pressure goes up. The animal defends itself and tries not to breathe. The second is the period of irregular respiration, deep respiratory movement and the water going into the stomach and the lungs. The first and second periods last one minute each. During that time the blood pressure drops a little. In the third period there is apnea and at the same time a drop in blood pressure. An animal can always be resuscitated if respiration is started before a very marked drop of the blood pressure. But if the blood pressure has gone down to 20 mm it is absolutely impossible to save the animal. These three stages correspond to clinical facts: (1) when the man breathes and his heart beats; (2) when the man does not breathe and his heart beats; (3) when the man does not breathe and his heart does not beat. To make sure at once whether the heart beats or not a needle is put into the heart to make an injection of epinephrine. Another point is to insufflate oxygen. That is why I said in my paper that although the Schafer technique is very good there is something better in advanced cases. Two things are done. Water is displaced so that oxygen can come in contact with the alveoli. The partial pressure of oxygen is increased, so that even if water cannot be displaced the chance is afforded the patient of finding a slight amount of oxygen available. Besides the intracardiac injection of epinephrine, massage through the chest must be done in order to keep on as much as possible the coronary circulation of the heart.

DR ALEXANDER O. GETTLER, New York. The increased chloride content of the left side of the heart simply means that the person was afloat when he reached the water. In about 500 cases that we have had in the medical examiners' office, the chloride test failed to work in only two as far as I remember. In fresh water of course the left heart blood has a lower chloride content because it is diluted by the fresh water. But the big point here is that when we get fresh water cases we always try to tell the person who is to do the autopsy to have the police or the detectives get a sample of the water in which the person was drowned.

The Problem of Carbon Monoxide Poisoning

DR HARRISON S. MARTLAND, Newark, N. J. There are from 900 to 1,000 deaths a year in New York City in the five boroughs from carbon monoxide asphyxiation. In 1928 there were 567 accidental illuminating gas asphyxiations and in 1932 there were 262. Those are cases amenable to resuscitation by artificial respiration. Suicides have been increasing. From 1928 to 1932 inclusive there were 5,000 deaths or about 1,000 a year from carbon monoxide. Coal gas doesn't amount to much. 74. The deaths from all causes during this five-year period were nearly 400,000, deaths from carbon monoxide forming 1 per cent of the total number and forming in 31,000 violent deaths 17 per cent of the violent deaths. The situation is similar in every large city of the country. More than half of these deaths are accidental. I believe that New York in the quick resuscitation methods due to propaganda to publicity and to this Society is

ahead of most cities in resuscitation. During the last five years in New York since the introduction of the inhalation treatment and the elimination of bad plumbing fixtures and the like there has been a reduction in the number of accidental illuminating gas cases. In carbon monoxide asphyxiation the blood must be 20 per cent saturated to cause symptoms. In cases in which resuscitation has been accomplished so that respiration is restored the carbon monoxide has been eliminated but the victims remain unconscious and die in coma from one to three days or gradually recover. Often in these cases futile attempts are made by giving blood transfusions or methylene blue, which do not do any good. The latter is not an antidote for carbon monoxide. The correct diagnosis at autopsy in such a case rests, especially if the case is seen about the second or third day after asphyxiation, on finding bilateral degeneration in the globus pallidus of the lenticular nuclei.

The treatment of carbon monoxide poisoning is what Henderson has already outlined. First, artificial respiration immediately by the prone pressure method or any other form of producing breathing, or of restoring breathing if respiration has stopped. Second, the inhalator treatment with a mixture of oxygen, by rescue squads, keeping the patient warm, and preventing muscular exercise. No transfusions of blood should be given. Neither hypodermic, nor intravenous injections seem to have the slightest influence and may do harm.

DISCUSSION

DR ALEXANDER O. GETTLER, New York. Qualitative tests for carbon monoxide are very good such as diluting the blood and noticing the pink color, and adding a little alkali and noting that the pink color remains, whereas normal blood changes to a brown or a greenish brown. The spectroscope affords another test through identification of the carbon monoxide bands. Some people think that the spectroscopic method is highly sensitive, but it is not. Carbon monoxide if mixed with good blood cannot be detected if the carbon monoxide is less than 8 per cent. I was interested lately in the normal carbon monoxide content of individuals. I tried to get people who had no carbon monoxide in their blood. That is hard to do nowadays because of the smoking of tobacco, because of automobile exhausts, and because of gases produced in industry and in the home. The atmosphere always has some carbon monoxide present. In New York blood from laboratory workers, hospital patients, clerks, salesmen and stenographers has shown an average of about 1 per cent. In street cleaners the average was about 3 per cent.

MR L. T. WHITE, New York. The company with which I am connected is the operating agent for a large oil company. It is our function to sell gasoline. The public does not appreciate the extent to which an automobile will make exhaust gases and carbon monoxide. We developed an instrument which told the combustion efficiency of a gasoline engine. In the past two years we have analyzed the efficiency of more than 250,000 engines. We were interested to note the figures on the pronounced causes of carbon monoxide death. While the automobile is killing 30,000 people a year, it is nonfatally injuring a million. We find that virtually 85 per cent of all automobile accidents are unexplainable. What is it that makes a good driver do a foolish thing such as driving his car off the highway into a pole or into another car? The insurance people were tremendously interested in this. They are losing \$14,000,000 a year on automobile insurance. It now costs more to insure an automobile for all forms of risk than it does to provide it with gasoline or oil. We are all interested in this, not only from the angle of preventing asphyxial death but also from the angle of preventing accidents and prolonging the automobile and its useful existence. In fifteen cities last summer we were amazed to find that practically every motorist interviewed noticed something which we inferred was a trace of carbon monoxide poisoning. We went out on the highways of Connecticut and flagged forty-three automobiles. We put into the automobiles a continuous carbon monoxide recorder capable of reading one part of carbon monoxide in 10,000 parts of air. We found measurable traces in 50 per cent of those cars. We found absolutely dangerous concentration in 7 per cent of the cars. We found that the concentrations were heavy when the car had some particular defect such as a broken gasket between manifold and exhaust

pipe, an open seam in the muffler, the muffler pipe terminating ahead of the rear wheels, and leaky spaces around the pit. The manufacturer should build his automobile to prevent these dangerous conditions. The public should be told what the symptoms of carbon monoxide are. The service companies should educate the public to the need of keeping motors in efficient condition.

Asphyxiation—A Basic Problem in Medical Education

DR WENDELL C. PHILLIPS, New York. It has been common knowledge in medical circles that many lives are lost each year by drowning, by carbon monoxide poisoning, by asphyxia of the new-born, by electric shock, by accidents of anesthesia and by drug poisoning. The conviction, however, that these fatalities are practically all due to asphyxiation is by no means so generally understood. While the total deaths due to these causes were deduced from available records, the conservatism of these deductions, suggesting an annual total of 50,000 deaths in the United States, contained so much truth that asphyxia as a major medical problem is everywhere finding acceptance.

In presenting this problem to the medical student at school, one must view it first as a basic problem of medical education the solution of which will probably require from ten to fifteen years. Secondly, it is to be viewed as an emergency problem. A continuous loss of 1,000 lives each week in the United States cannot be regarded with equanimity.

As a basic problem in medical education asphyxiation may be dealt with in the curriculum of the medical school, first by a policy of segregation in which emphasis is placed on all matter in the departments of anatomy, physiology, therapeutics, thoracic surgery, pathology, electrodynamics and any other department which may have a bearing on asphyxiation, and, secondly, by pursuing a policy of integration in which a new department is organized for the specific study of all matter dealing with asphyxiation.

The foregoing is merely suggestive. The head of each department must be personally approached and his interests aroused before he can be expected to emphasize this matter. The chief resistance to the second approach to this problem by a process of integration is the objection that already there are too many departments. The treatment of asphyxiation in the many fields in which it occurs presents one common factor, and this is that gases are used as the major therapeutic measure. This view, suggested by Yandell Henderson in 1928 provides a common ground and deals with the closely related activities known as resuscitation, anesthesia and oxygen therapy. It would appear that the personnel must be trained and equipment provided from the vantage point of a new department organized for the purpose of meeting an actual need in the medical field. When an asphyxial accident occurs in the ward, a trained physician capable of applying modern methods of resuscitation should always be available. Trained personnel for this work is daily functioning in the department of anesthesia since the anesthetist is familiar with the care of the unconscious patient and has a substantial groundwork on which refinement of technique may easily be added. Such a functioning department would immediately lend protection to the now uncovered fields of resuscitation and oxygen therapy. The importance and the dignity of this office would promptly be recognized and authority that is now lacking would be conferred. The director of such a department would be interested to assemble facts relative to the scientific and technical treatment of resuscitation and the problems of internal medicine as they are now faced in oxygen therapy.

A policy of integration designed to reduce the present mortality from asphyxiation as applied to the curriculum of the medical school appears to offer the greatest hope of relief.

DISCUSSION

C. R. REYNOLDS, Colonel, M. C., U. S. Army. While the medical department of the army is spread out in stations in the United States, Alaska, the Philippine Islands and Puerto Rico, it is at the headquarters represented by the Surgeon General's Office and the Army Medical School that most can be done. It is there that the principles of training are formulated and passed out in the service. From the standpoint of therapy, medical officers go along with the medical profession. They come to the army as doctors. The training they get at the Army Medical School is in the nature of a postgraduate course.

I believe it is just there that greater emphasis can be given in the matter of anesthesia and oxygen therapy. I believe right there is where the greatest effect can be made in putting over the principles of this society in the military service. We in the medical corps are constantly training R. O. T. C. students at the medical schools. We get them in camp for about six weeks during their college course. There they are given training in first aid and principles that have been discussed here. We also train many thousands of the C. M. T. C., boys between the ages of 17 and 21. There again is a great opportunity of putting over a training program. We come in contact also with a large number of reserve officers. There are something like 17,000 men of the civil profession who come to the army from year to year to receive special training. It is among those that we try to emphasize the matter of first aid and the care of the injured. We come in contact with the national guard. It is in that field I think that the army medical corps can do its greatest work in emphasizing the matter of resuscitation. I believe a real step can be made by emphasizing the importance of the subject to the surgeon general and to the officials of the Army Medical School.

DR L. F. ANDERSON, Buffalo. In the hospital with which I am connected we have adopted a plan that no one but a legally qualified physician shall administer anesthetics. Each intern is put under the instruction of one of our anesthetists on the staff. Each year we are turning out interns capable of giving gas anesthesia and doing a certain amount of work in oxygen and in carbon dioxide therapy. It is regrettable to my mind that in the great teaching centers in some cities the instruction of physicians in anesthesia, in oxygen therapy, is left to the nurses. The time is at hand when it should be a legal measure that only qualified physicians should be allowed to administer anesthetics or do gas therapy.

The Sound Picture as a Medium of Instruction

F. L. DUFFREUX, New York. An educational talking picture must be the result of the preparation of scenarios that have stood the test of group discussion. It must grow out of production techniques that take advantage of the latest scientific developments and must be the result of tests and measurements that serve as guides to the best use of attention-directing and interest-arousing devices. Fortunately, for the past five or six years a serious development of standards for educational picture has resulted. Research procedures have been well established and methods of production are available today, so that a picture can be made with a reasonable certainty that it will accomplish the objective desired. As proof of that three experiments were conducted—one by Dr. Arnsperger of Teachers College, Columbia University and one by Dr. Rulon of the Graduate School of Harvard University, and one by Dr. Stoddard, superintendent of schools of Providence.

The Arnsperger experiment involved children in six, four schools, 3,600 children all told, with a controlled experimental group, one with the talking picture and one without the talking picture. Columbia University has published a book showing that the children with the picture gained 25 per cent more in the Arnsperger experiment than the children without the picture and that on a recall, a retention test of six months later, the children who had seen the picture retained two thirds more than the children who did not.

The experiment of Rulon at Harvard is a confirmatory experiment.

Dr. Stoddard at Providence took 200 junior high school students in an auditorium with a teacher and the talking picture. He had 200 children in an auditorium with a teacher and no talking picture. The result of the experiment was that the children in the auditorium with the picture gained probably 12 or 14 per cent more than even the best conducted class of thirty-five that was in the school.

There is no picture relating to asphyxia, but at Dr. Flag's suggestion I have put together four typical pictures, not one of which relates specifically to this field. One of the pictures shows how it is possible to deal with abstract problems in connection with asphyxiation such as the diffusion of gases taking place in the airway, the matter of partial pressures on which the percentage of oxygen depends, and the matter of vapor tension and the well known fact of atmospheric pressure. Also,

the effects of cold and heat on the behavior of gases and the effects of pressure. The prevention of asphyxial death, is a subject that demands the use of a medium that will dramatize the possibilities and compel people to think seriously about this important work of prevention. The problem calls for the use of a medium that will save time in the dissemination of the essential ideas. In this respect the educational talking picture presents an outstanding opportunity for a worthwhile contribution to the health and well being of millions of people.

Negative Pressure Cabinet (Respirator) Treatment of Asphyxia

DR DOUGLAS P. MURPHY, Philadelphia. I understand that the words "negative pressure" constitute a wrong term, because any pressure that is above zero isn't negative. But the terms used generally, so I will assume that it is any pressure subatmospheric.

Artificial respiration carried on by varying the air pressure on the surface of the body was described first by Doe in 1889. Devised for the treatment of asphyxia of the new-born his apparatus consisted of a box covered at one end with a piece of sheet rubber. The apparatus as used by Doe in the period of 1888 and 1889 was simply a wooden box and across it was a piece of sheet rubber with a hinge at one edge and a hook on the other edge. The infant was placed into a plaster mold and the mouth and nose were applied to the opening in the rubber and then the attending obstetrician would merely suck and blow on the piping connected with the box. With this apparatus it was stated that some fifty patients were treated.

Mechanically induced changes of pressure were employed clinically by Drinker and Shaw in 1929. Their apparatus differs in principle from that of Doe in that the head of the patient protrudes from the box through a snugly fitting rubber collar and the variations in air pressure are produced by an electrically driven pump and valve arrangement.

The mechanically operated negative pressure cabinet is limited either to the treatment of patients who are stricken with respiratory weakness or paralysis in institutions possessing such a machine or to patients who can reach a machine before death occurs. The respirator also should be limited to the treatment of individuals whose upper air passages are clear. The respirator as an instrument for initiating and maintaining artificial respiration operates primarily by producing a subatmospheric pressure on the thoracic walls. When this occurs, the lungs are inflated by the force of the normal or atmospheric pressure acting through the subject's nose and mouth which are outside the negative pressure cabinet. Release of the negative pressure in the cabinet with a return here to atmospheric pressure, permits the expanded respiratory muscles to contract and thereby to expel the air forced into the chest by the atmospheric pressure outside the cabinet. Repetition of these changes produces respiratory movements. To ascertain that death has occurred, it may be necessary to open the cabinet—which interrupts the treatment—and auscultate the heart. The difficulty encountered in getting at the body without interrupting treatment is a disadvantage of this method of artificial respiration. If the heart continues to beat, though spontaneous breathing does not take place treatment naturally should be continued indefinitely.

I observed an infant who was badly asphyxiated. During the first five minutes the child took no breath. During the second five minute period it took two breaths during the next five minute period approximately five, then six, then four and then eight, and so on, until at the end of an hour and a half the rate of breathing became too rapid to record and the respirator was stopped. The respirator has made this opportunity available to study the physiology of the return of the respiration in the asphyxiated infant.

It is not known how much damage the asphyxiated infant receives if it is asphyxiated for a long period. I refer to the damage that may or may not occur to the brain cells. In after life, many people show signs of deterioration or retardation in various things. As far as I know there are no studies that have carefully correlated the inadequacy of breathing or the damages that occur at birth with troubles which follow. It would seem to be wise not knowing what will happen, to try to supply to the new born infant as nearly as may be an ade-

quate aeration from the time the infant begins to gasp until the breathing activity has a normal rate or amplitude or both.

Whether Dr. Flagg's method or the respirator or whatever one uses, one should continue to use it during the period when it is possible that the breathing mechanism is not supplying an adequate amount of oxygen. Certain asphyxiated individuals, though their cardiac action continues, fail to develop spontaneous respiration in the negative pressure cabinet. Others possessing a small amount of respiratory power become progressively worse. In such cases the inexperienced attendant frequently feels called on to increase greatly the degree of negative pressure. Any great increase in this pressure is unwise. It is quite dangerous to do what one shouldn't do in the treatment of individuals who appear to be failing or who are not beginning to breathe. Extremely serious damage can be done by these high degrees of negative pressure. To the conscious individual or to the one with a certain amount of muscle tone, there is enough checking of the inspiratory movement to prevent that, but it is extremely exhausting to the individual. If a patient is unconscious and has no control, one can expand the chest to such degrees as to rupture every alveolus in the lung. It is important, therefore, that the use of so powerful an instrument as a respirator be operated only by a person familiar with its potential danger.

If asphyxia is caused or is aggravated by an unusual increase in intracranial pressure due to cerebral congestion or intracranial hemorrhage, the use of a respirator should tend to relieve the cerebral congestion and thereby reduce the intracranial pressure.

There seems to be no contra-indication to the use of the negative pressure cabinet in the treatment of any adult or infant suffering from respiratory embarrassment, except in the case of individuals whose upper air passages are obstructed. In its use the subject is exposed to no force that cannot be both controlled and measured.

DISCUSSION

DR PALUEL J. FLAGG, New York. Some years ago I became associated with Dr. Chevalier Jackson in the perfection of a technic for anesthesia for operations about the head and neck. This technic consisted in a simple equipment for laryngoscopy for apparatus designed to supply suction, and for especially designed tubes that might be intubated without trauma and with which oxygen and carbon dioxide could be delivered under measured pressure. It is unfortunate that this technic should have come to be associated with my name because all that I contributed was the construction of a pocket flashlight laryngoscope which does away with the resistance offered by the small-wired laryngoscope used for bronchoscopy, by the suggestion that it is essential to supply facilities for suction in all cases and by the assembling of a delicate water manometer. I would like to make it plain that no officer of this society is in any way interested in the sale of any equipment. When this society was organized we clearly emphasized that point and renounced all commercial connections with all equipment so that any reference I make to equipment which happens to bear my name has no strings to it. The question of suction is vital. I would suggest that when one wants suction that will work perfectly, one use the mouth suction with a bell tube under direct vision.

In submersion work it has been found that one of the most effective sources of suction is the suction supplied by the intake manifold of the engine which one can attach immediately through connecting with the windshield wiper. An ambulance at the Coney Island Hospital was equipped for one summer. We chased submersion cases every Sunday during that one summer. We had a bus equipped with a suction line to the intake manifold and we had a powerful suction always attached to the car and instantly available on an idel engine. Another form of suction consists of a suction produced by fluid falling from one bottle into another. The height of the drop and the speed of the volume flowing determines the amount of the suction. This suction is available on a beach where there are no facilities at all in the way of our ordinary equipment. It can be attached to a post on one of these observation stands, as one sees at Coney Island. When the contents of the bottle have fallen out it swings around and the bottom bottle comes at the top, and one has to continue suction.

The question of insufflation was one that we devised from the ground up. Nobody knew anything about the size of the tube or the length of the tubes what the baby would tolerate, or anything about it five years ago. The diameter of this tip is approximately 3 mm. The tube is velvetized, and repeated intubation in the same infant for long intubation, checked up postoperatively, post mortem, shows no irritation. We lubricate our instruments in all intubations with sterile oil or petrolatum and we have no postoperative intubation irritation. The adult tube is merely a shortened bronchoscope. Laryngoscopy of the asphyxiated patient the anesthetized patient is an entirely different procedure than laryngoscopy of a normal patient with cocainization.

The medical relief of asphyxiation turns on the pivot of prompt laryngoscopy and intubation. Furthermore, with such a procedure one can immediately introduce oxygen and carbon dioxide under measured pressure and get effects at once which one strives to get over a long period with the prone pressure Schaefer method or with the use of an inhalator.

DR JOHN D. KERRON, New York. I find that very few practitioners know how to use a laryngoscope. They regard it as sort of a piece of magic that is to be learned only by the especially gifted whereas almost any one having the amount of intelligence that an educated physician is supposed to have can learn to use a laryngoscope efficiently. In using the laryngoscope to find out what the trouble is one may find possible laryngeal abscess, abscess of the tongue, abscess of the lingual walls of the pharynx, and so on. At times in face of infection of the neck it isn't the best thing to do a tracheotomy on account of the danger of introducing septic material into the lungs. I have been an advocate of preceding tracheotomy by the use of the bronchoscope or by the use of one of these tubes because a tracheotomy in the face of impending asphyxiation is very difficult to do. I want to urge education of the profession to use the laryngoscope and to use the bronchoscope or the intubating tube for purposes of overcoming temporarily laryngeal obstruction and as a measure preceding tracheotomy.

DR ETHAN F. BUTLER, Elmira, N. Y. The point of a tracheotomy with the bronchoscope in position is important. I believe that if a few minutes of extra time has to be expended placing the bronchoscope in position there will be regained twice as much in the speed of accomplishing tracheotomy and preventing an undue flooding of the lower airways with blood and other secretions. This to some extent is pioneer work. All pioneers have a certain element of obstruction and inertia to overcome. To what extent communities are going to be prepared to meet the sudden, unforeseen emergencies of threatened or actual asphyxiation has got to depend largely on community reaction to these problems. There will be a tremendous inertia to overcome but as the years go on the community attitude will be 'Let us be prepared so that even the few asphyxial deaths that may be expected in our communities can be reduced.'

DR DOUGLAS P. MURPHY, Philadelphia. Every new-born child, whether one withdraws fluid from the trachea or from the pharynx or doesn't touch it at all, should be kept head down below the horizontal for perhaps the first twenty-four or forty-eight hours. I feel certain that if the group that is producing artificial respirations with submersion cases would add to the situation the keeping of the individuals head down for a considerable time so that the fluid will gravitate to the nasal pharynx, it will save more lives.

Neuropathology Attending Asphyxia from Carbon Monoxide and Atmospheres Deficient in Oxygen

DR R. R. SAYERS, Washington, D. C. DR JOHN CHORNYAK, Pittsburgh and W. P. YANT, Pittsburgh. The chemical and pathologic reaction of dogs to asphyxia by carbon monoxide and by atmospheres deficient in oxygen was studied recently by the U. S. Bureau of Mines and the U. S. Public Health Service. This study was conducted to obtain information on the response of the organism to asphyxial environment, with the idea of devising a procedure for treating moribund cases of carbon monoxide poisoning that do not respond satisfactorily to present methods. The scope of the investigation includes the reactions attending comparatively rapid asphyxia and comparatively slow, prolonged asphyxia. In some of the experiments

the exposure was continuous until death occurred, in others it was terminated when the first indication of terminal symptoms was observed. Some of the animals recovered from the acute effects and others died within from a few hours to three days. The ones that recovered were kept for observation for periods ranging from a week to five months. Autopsies on the animals were held immediately after death and the brains were removed. The brain in the gross was very edematous and markedly congested. The most striking finding was a severe perivascular and perineuronal edema, which was marked in the corpus striatum, the cortex, and the dorsal motor nucleus of the vagus nerve. The vessels were greatly dilated and tightly packed with red blood cells. This stasis was marked throughout. There were a few petechial hemorrhages, especially in the corpus striatum and cortex. Most of these were no larger than would occur by diapedesis through the dilated vessels. Occasionally a few leukocytes, both lymphocytes and polymorphonuclear leukocytes, were found in the perivascular spaces. The endothelium of the capillaries appeared to be swollen in some areas.

The neurons were extensively damaged. Many of the nerve cells seemed to have been ruptured. In some areas all that appeared to be left of the nerve cell was a swollen, distorted and vacuolated nucleus with a little Nissl material around it. A clear space marked the site of the original cytoplasm of the neuron. In other areas there was a marked central chromatolysis with distorted nuclei. Not all the cells in the same brain were equally damaged. There was a variation in the degree of damage with different animals exposed to 0.6 per cent carbon monoxide for from twenty to thirty minutes. With three of the four dogs studied the variation was not marked, but the fourth showed distinctly less damage. The foregoing conditions were, however, present to some degree in all the animals.

The lesions due to eight and fifteen hour exposures to from 0.18 to 0.22 per cent carbon monoxide differed in degree only from those described due to comparatively rapid carbon monoxide asphyxia or exposures that caused death in from twenty to thirty minutes. The circulatory changes, such as dilatation of the vessels, stasis and perivascular edema were marked in the long exposures. The hemorrhages were also more frequent and more extensive. In many of the hemorrhagic areas as well as in some of the extremely dilated vessels the red blood cells had undergone disintegration. The perivascular areas, especially in the meninges, were infiltrated to a greater degree with leukocytes. The edema in the medullary substance was much more severe in many areas giving the medullary substance a very loose mesh like appearance. There was an increase in number as well as in size and an occasional difference in shape of the neuroglia. Occasionally, very large clear spaces were found throughout the medullary substance. These were not observed in the animals that died after from twenty to thirty minutes of exposure or in unexposed controls.

The degenerative changes of the neurons in general were also more severe in the long exposures. There were areas, especially in the cerebral cortex and the corpus striatum that were apparently completely destroyed. The results of this study substantiate the belief that the damage incident to carbon monoxide is diffuse. It is not specific for any one area of the brain although not all types of cells in any particular area are equally affected.

The neuropathologic changes produced in six dogs by fatal exposures of from fourteen to thirty-five minutes and in four rats by fatal exposures of from twenty-eight to seventy-two minutes to atmospheres deficient in oxygen was studied. The circulatory changes in the dog were characterized by dilatation, stasis involving the entire capillary system, and perivascular hemorrhages.

There is a marked difference in the susceptibility of the nerve cells to oxygen deprivation. The cells of the cortex, especially those in the outer granular layer, thalamus, sensory centers and those in the outer granular layer, thalamus, sensory centers and the visceral correlation centers throughout the brain stem and the visceral efferent nuclei are the most sensitive. There was a marked difference in the reaction of the nerve cells of the rat as compared with those in the dog. There are two general types of degenerative changes in the nerve cells following asphyxia. Some become shrunken and stain diffusely, others show varying degrees of chromatolysis. These observations on the differences in the reaction of dogs and rats to atmospheres deficient in

oxygen are in general in line with the current neurologic views on cerebral mechanisms. They also reveal the serious difficulties that are encountered in formulating theories on cerebral mechanisms in human behavior from data on rats.

The Factor of Chemical Injury in Asphyxia

LEON A. FOX, Major, M. C. U. S. Army. The chemical agents used in war are not insidious, nonirritating agents like carbon monoxide and hydrocyanic acid. They are on the contrary violent respiratory irritants. A great many deaths listed as due to chemical injury are really asphyxial deaths. Exposure to concentrations of many chemicals for periods that produce unconsciousness and cessation of respiration can be very promptly recovered from if the patient is removed to an atmosphere free from the contaminating agent and given a brief period of artificial respiration. Fortunately, there are not a great number of agents that are so insidious and difficult to detect as carbon monoxide. However, the toxic chemicals that do give some warning, but insufficient to provide adequate protection are all too numerous. Hydrocyanic acid gas is such an agent. Hydrogen sulphide is another. There is a large group of anesthetizing hydrocarbons that may produce casualties. Some are used as anesthetics in medicine. Many more are required by industry. In addition there are the halogen substitution products of this great group. These halogen derivatives are also frequently encountered in industry. Carbon tetrachloride, tetrachlorethane and trichlorethylene are well known examples of this group.

A special group of agents has been added to the list of chemical hazards. I refer especially to the refrigerating agents that are employed in the circulating systems of modern refrigerating plants.

In a very few instances it is believed that airplane accidents have resulted from pilots being overcome by carbon monoxide. The army gas mask does not provide protection against carbon monoxide.

Carbon dioxide may be a most important factor in producing asphyxial death. It must be remembered that while 7 per cent of pure oxygen can be replaced with carbon dioxide with great advantage to the patient in some resuscitation work, 7 per cent of the oxygen present in air cannot be replaced with carbon dioxide. If the 20 per cent oxygen in air is replaced with any large part of carbon dioxide, symptoms of severe anoxemia are presented and asphyxia may ensue. This is not carbon dioxide injury. This is pure oxygen privation. The substitution of carbon dioxide for the oxygen in the atmosphere produces the chemical hazard.

Cyanide deaths are especially sad for in many instances they occur under conditions that are entirely preventable. The army gas mask, equipped with the regular canister, should not be used to provide protection against cyanide poisoning. A special canister is prepared for use with the mask to neutralize this toxic agent.

Many casualties are caused by exposure to the violent lung irritants such as chlorine phosgene, sulphur dioxide, nitrous fumes and other acid radicals as well as injury from ammonia and other respiratory irritants. Immediate asphyxia is not an extremely important factor in these injuries. These caustic agents actually unite with and destroy the respiratory tract by their direct chemical activity when heavy concentrations are encountered.

On exposure to concentrations of lung irritant gases that are less powerful, respiratory irritation and embarrassment immediately occur, but if the patient is removed from the contaminated atmosphere these symptoms promptly subside. Dangerous symptoms develop later. These patients often have a period of comparative freedom from all symptoms. Then from two to four hours later, possibly even twelve to twenty-four hours later, symptoms of severe lung edema develop. Ordinarily these patients are in the hands of medical attendants long before these symptoms ensue. These attendants should always remember the danger of delayed lung edema in such cases. Cases of this type of chemical injury have been prematurely discharged from the hospital with fatal results. One must never let enthusiasm for special agents have the effect of diverting attention from the proper general treatment of all cases that present symptoms of asphyxia. Cessation of respiration whatever the cause is a symptom incompatible with life. It must be remembered that

the first last and most important therapeutic step is to pump oxygen into these individuals—if only air is available, by means of artificial respiration.

Problems of Respiration in Naval Medicine

L. W. BROWN, Captain, M. C. U. S. Navy. There are situations peculiar to naval medicine which group themselves around the problems of respiration. These are illustrated in submarine ventilation, deep sea diving, altitude flying, naval gas warfare and accidental conditions in which oxygen deficiency or gas poisoning is encountered. In all these situations the limiting factor is human respiration and many have undergone recent developments of particular significance to the naval medical officer. During the past five years, ten persons have been killed and additional nonfatal casualties have resulted from entering compartments of naval vessels which have been sealed for prolonged periods and without prior ventilation. Additional cases have been reported within recent years from the British admiralty. In all these instances men had entered such spaces without taking the precautions laid down in the regulations.

Reports have been made in the literature of sudden death from men entering the holds of merchant ships that had been hermetically closed for long periods, but in these instances the atmospheric changes were due to decomposing fruit, grain or other vegetable matter. The recent cases in the U. S. Navy have occurred in connection with virtually empty spaces, notably in ship's blisters and submarine pontoons. The so-called blister is a characteristic of the modern battleship developed since the World War and designed for torpedo defense. It consists of a false hull overlying the original hull reinforced by transverse and longitudinal frames and conforming to the longitudinal lines of the ship. The maximum depth of the blister is about 40 feet from top to bottom. The blister is subdivided into twenty sections of two compartments each on either side of the ship, with manholes provided for communication. There are a total of eighty blister compartments. The interior is painted and kept hermetically closed to insure water-tight integrity except for inspection and possibly renovation at intervals of six months.

In a blister compartment on the U. S. S. *New York* in 1929 the manhole cover was removed and an officer and three men entered without the precaution of preliminary ventilation. Just as the officer entered the lower compartment of the blister he fell to the bottom, apparently overcome. The three men with him immediately descended the ladder to his assistance and all three collapsed. Two additional persons reaching the bottom were also incapacitated. Ultimately nine persons were incapacitated and the officer and one man died. The symptoms of those recovering were diagnosed as due to carbon monoxide. The blood of the two who died was positive for carboxyhemoglobin. Another disaster occurred incident to entering a compartment of a submarine pontoon in December, 1931. The pontoon is a metal drum designed for the raising of sunken submarines. The compartment had a capacity of about 1540 cubic feet and was ventilated for a very brief period but not adequately, as required by regulations. Three men descended and were immediately overcome. Three additional men were incapacitated in attempting to rescue their co-workers. The first three men were dead when finally removed.

Belli, by experiments in the Italian navy, showed that the oxygen in a ship's double bottom can be reduced to 3 per cent by the use of red lead paint.

Gardner pointed out that, when linseed oil or similar drying oils are spread in thin layers the absorption of oxygen which takes place on drying is accompanied by the evolution of carbon dioxide and organic substances, carbon monoxide also being evolved in small amounts.

A study of the vitiation of the air of confined spaces of naval vessels by different types of paint containing linseed oil has been in progress at the Puget Sound Navy Yard for the past two years. Additional studies are in progress with an experimental test tank fitted with sixteen removable plates of definite area for coating with different types of paint. It has been determined with a linseed oil paint that oxygen absorption and carbon monoxide emission no longer occur after an exposure of approximately eight days. A ventilating period of ten days after painting would therefore remove the hazard of dangerous vitiation on closing such a blister. As would naturally be anticipated,

the use of a bituminous paint free from linseed oil does not change the contained atmosphere. It has been calculated that a 15-inch gun with its charge of 400 pounds of smokeless powder will give off 2,500 cubic feet of carbon monoxide each time the gun is fired. If for any reason any portion of the gases are permitted to blow back into the turret in which the gun is mounted, the carbon monoxide will produce symptoms. This is normally prevented in the U. S. Navy by means of an automatic air blast, which instantly clears the barrel of all traces of explosion gases. However, aboard *H. M. S. Iron Duke* in 1930 three men were overcome by fumes blown back into a turret during the firing into a head wind of 6 pounder subcaliber guns after approximately eighty rounds. These cases were diagnosed as carbon monoxide poisoning. All the men recovered.

Fairlie has reported a study of powder gas casualties in the World War. Eleven casualties, two of which were fatal, resulted from nitrous fumes in the battle of Jutland. Seventeen cases, with fourteen fatalities occurred in 1916 aboard *H. M. S. Russell* as a result of fire and explosion incident to contact with mines. Fifty-six cases were reported from *H. M. S. Britannia*, with twelve fatalities, following torpedoing of the ship and a subsequent fire in one of the magazines. The clinical reports of these disasters emphasize the period of latency, which is an outstanding aspect of poisoning with nitrous fumes as after poisoning with phosgene a chemical warfare gas. The initial symptoms of irritation may be comparatively slight and pass off readily, to be followed by severe or even fatal pulmonary edema after a variable interval. Many of the patients from the *Britannia* were landed apparently in normal condition and carried on for many hours before serious signs developed. The latent period of these cases averaged from ten to twelve hours.

The *Mississippi* disaster in our navy in 1924 resulted from the accidental ignition and therefore burning of a powder charge in a turret mounted with 14-inch guns during target practice. Forty-eight men were killed only two persons in the turret surviving. The head and hands of practically all the dead showed signs of burns but in the majority of instances not sufficient to account for death. Evidences of asphyxiation were present, although no blood examinations for carboxyhemoglobin were conducted.

About four months later a similar accident with burning powder occurred aboard the *U. S. S. Trenton* involving the forward twin gun mount with a total loss of fourteen men only five of those exposed having survived. The blood was examined for carbon monoxide hemoglobin in all of these cases with negative results. This result with reference to the survivors did not appear consistent, although the period of exposure to the fumes was short. Death was generally ascribed to extensive burns and shock.

The question of the possible hazard of carbon monoxide in relation to aircraft was exhaustively studied by the Bureau of Medicine and Surgery in conjunction with the Bureau of Aeronautics. It was concluded that in some types of airplanes, depending on the arrangement of exhaust leads, fuselage, and so on, carbon monoxide is carried back to the cockpits in sufficient concentration to result in as much as 15 per cent saturation of the blood of the pilot and other occupants of the airplane. Although the highest saturation of blood obtained during the study would not be sufficient to render a person unconscious, the absorption of even minute amounts of carbon monoxide is highly undesirable, owing to the possible effect on the efficiency of the pilot. It was evident that a definite hazard existed in this regard. Immediate steps were taken to eliminate the carbon monoxide by a simple and inexpensive modification of the exhaust leads of those airplanes. The specifications now prescribe that all new airplanes in the future shall be tested at the factory for carbon monoxide and if present eliminated before final acceptance by the navy. The submarine is propelled on the surface by means of the Diesel engine and in the submerged condition by the electric motor. The electric current is furnished by 120 storage batteries to each vessel. Owing to limitations of weight and space air-purifying equipment must be reduced to a minimum. It is therefore impracticable to maintain the atmosphere of a submarine at the normal atmospheric concentration of 20.9 per cent oxygen and 0.03 per cent carbon dioxide. In the majority of submarines of the U. S. Navy the carbon dioxide will ordinarily not reach 3 per cent until the end of seventeen hours. Air

purification therefore is not used unless longer periods of submergence are contemplated. Under ordinary conditions the periods of submergence are so short that purification is not required. It is of course a comparatively simple matter to calculate the time of submergence required to reach the limiting figure of 3 per cent carbon dioxide on the basis of the average volume of carbon dioxide exhaled hourly per man and the cubical capacity of the contained air of the vessel. Under the conditions of a disaster such as that of the *S-4*, which sunk off Provincetown in 1927, the electric power is practically always out of commission and forced ventilation therefore stopped. In the *S-4* disaster, six persons were trapped in the torpedo compartment without provision for removal of carbon dioxide. The last signal received by divers from the survivors was seventy-five hours after the collision. It is estimated from the cubical air space of the compartment and the approximate hourly output of carbon dioxide at rest for six men that a concentration of approximately 9 per cent was reached. Life at least existed under these conditions.

The accidental access of salt water to the electric storage batteries of a submarine evolves chlorine gas. A special type of gas mask designed for the specific purpose of protecting against chlorine is provided for all personnel.

The submarine escape apparatus has been adopted for individual escape from submarines. The mechanism of action consists of a rubber bag of approximately the cubical capacity of the human lungs, connected above to a mouthpiece with inhalation and exhalation tubes, and provided below with an escape valve through which the expanding air escapes during ascent. A small canister of soda lime is included for the absorption of carbon dioxide. Preliminary to the donning of the appliance for escape the compartment of the sunken submarine is flooded with sea water, compressing the air therein to the pressure of the outside sea and thereby allowing for the opening of the hatch of the compartment. The breathing bag of the escape appliance is then filled with oxygen and the mouthpiece is inserted in place. The individual then ascends along a buoy line at a prescribed rate. If the rate of ascent is excessively rapid, particularly if the subject withholds his breath, there is a distinct hazard involved in that a dangerous rise of intrapulmonary pressure may develop. Thus far in training with the submarine 'lung' two fatalities and eight other cases of cardiovascular collapse have been reported under these conditions. It is concluded that these injuries were due to air embolism.

DISCUSSION

DR. M. H. FOSTER, New York. In our work in the Public Health Service we are chiefly concerned with deaths from hydrocyanic acid gas. In quarantine work the problem is to be certain that our ships are free from the gas before we allow the personnel to go back into the ship and go down into the hold. They use a test paper and simply throw sheets of this paper down into the hold and watch its behavior. It is a bright yellow copper, and if it turns pink rapidly it is a good thing to keep out of there. If it turns pink slowly it is safe for one of the disinfectors to go down. These men do not wear gas masks and they do not depend on anything else except their sense of smell. When they get down there if they don't smell too much of the hydrocyanic acid gas they feel free to go ahead with their work. It depends a great deal on the temperature and the humidity, on whether or not the ship is in motion, and on how much cargo there is in the hold. If one can get the ship under way and let it go for three or four miles against the wind it will blow out. We had one fatality, of a child who was placed on a bed and allowed to sleep on a pillow against our instructions.

DR. R. R. SAYERS, Surgeon, U. S. Public Health Service. There has been protective equipment developed gas masks and the oxygen breathing apparatus. Every one of these has its limitations. If you will put a rope onto a man if you are going to let him down you can pull him back out again, whether you are on board ship or whether you happen to be on a farm going down into a well. The first thing is to find out whether you can go in safely or not. Davis developed a safety lamp used in the mining industry which will tell when a flammable gas is available. One can use a bird, a mouse or a cat. Lower the animal into the compartment and

are going in. After it has been there a few minutes if it gets along all right it is probably safe for you to go in. Then if you are going to go in and are still not sure about it, you ought to have a rope around you, and you ought to have somebody on top big enough and strong enough to get you out again. That method is being used in industry quite regularly.

DR E W BROWN, Washington, D C. Answering Dr Foster's question in regard to the training in the use of the escape apparatus, we have a systematic course of training for submarine personnel. They must qualify in the use of the apparatus to remain in the submarine service. Some of our trained personnel have ascended 100 feet without the use of anything. They have simply gone down in the submarine bell in this tank and the ascent is made without any lung apparatus whatever. It involves of course a rather spectacular aspect of training. We don't advocate that of course as a means of escape but merely as an emergency.

Current Medical Literature

AMERICAN

The Association library lends periodicals to Fellows of the Association and to individual subscribers to *THE JOURNAL* in continental United States and Canada for a period of three days. Periodicals are available from 1925 to date. Requests for issues of earlier date cannot be filled. Requests should be accompanied by stamps to cover postage (6 cents if one and 12 cents if two periodicals are requested). Periodicals published by the American Medical Association are not available for lending but may be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

Titles marked with an asterisk (*) are abstracted below.

Hemorrhagic Eruption of Mouth in Rheumatic State—Holtz and Friedman observed an enanthema consisting of an eruption of hemorrhagic spots in the mucous membranes of the mouth and throat of patients with rheumatic heart disease, also in other diseases included in the concept of the rheumatic state and in relatively few patients in whom there was no apparent rheumatic infection. It has been seen more frequently during the course of rheumatic heart disease than in any other condition and the seasonal peak of its frequency in this disease coincides with that of acute infections of the upper respiratory tract and carditis. In nineteen cases of rheumatic valvular disease of the mitral and aortic valves examined at biweekly intervals for four months hemorrhagic spots were found in nine cases at the initial examination and in a total of thirteen cases during the period of study. Of twenty-nine cases without rheumatic valvular disease, chosen at random for control, spots were found in only one case.

Differentiation of Coronary Thrombosis from Pulmonary Embolization—Averbuck observed six patients who were presumed to have had fatal attacks of coronary artery

thrombosis but in whom necropsy revealed that they had succumbed to pulmonary embolization. In two instances the diagnosis was difficult in that coronary artery disease had previously been present. Death was caused by a pulmonary embolus. In the other four cases no previous evidence of coronary disease had been present, but death was shown at necropsy to be due to pulmonary embolus. The author believes that, when the clinical picture suggesting coronary artery thrombosis occurs in a female patient who has neither arterial hypertension nor diabetes, a pulmonary embolus should be suspected. The high incidence of embolic phenomena in the female sex arising from abnormal pelvic conditions is an important factor. If the history suggests previous evidence of peripheral vascular involvement, i.e., phlebitis, unilateral leg edema, pelvic disease or abnormalities of the lower extremity, the likelihood of the coronary syndrome being caused by an embolus to the lungs is strengthened. Postoperatively, the clinical picture of pulmonary embolus readily simulates coronary thrombosis. When one recalls that pulmonary emboli are frequent after operation and that coronary thrombosis is comparatively rare because patients having coronary disease are spared any but emergency surgical procedures, such cases will be correctly analyzed. In a hyposensitive individual, when the diagnosis of coronary artery thrombosis is made in the absence of pain, and dyspnea is the principal sign, the possibility of a pulmonary embolus must be excluded. The conditions may coexist.

Renal Amyloidosis in Relation to Renal Insufficiency—Dixon found 100 cases of renal amyloidosis in 9,613 consecutive necropsies. Tuberculosis of the lungs (70 per cent) and bones (8 per cent) was the etiologic disease in 78 per cent of the cases. The highest incidence of renal amyloidosis occurred in the third decade of life. Twelve of the forty-six cases in which sufficient evidence was available were associated with renal insufficiency. Obstruction of the glomerular capillaries by amyloid deposits is a factor in the causation of renal insufficiency. Hypertension is relatively infrequent in amyloid disease of the kidney. Of thirty-five cases with blood pressure readings, the systolic pressure was above 150 mm of mercury in only four (12 per cent). In the cases of renal amyloidosis with renal insufficiency, the kidneys were either normal in size or somewhat enlarged. Renal amyloidosis may occasionally be associated with independent arteriolar nephrosclerosis. Albuminuria is a fairly constant observation in renal amyloidosis.

Epidermomycosis and Flatfoot—The Lieberthals noticed in a large series of cases of mycotic infection of the feet that a moderate to advanced degree of flatfoot was present also. Of their 195 patients, 90 per cent had flatfoot and 30 per cent also had hyperhidrosis. The authors believe that as a result of the changes of flatfoot the resistance of the skin itself is lowered and the soil thus prepared for the invasion and subsequent growth of the fungi in epidermomycosis. Ten advanced and five moderately advanced cases of vesiculopustular lesions on the soles as well as intertriginous changes, accompanied by flatfoot, responded more rapidly to the ordinary forms of treatment after orthopedic correction. Not only did the lesions of the skin clear up rapidly but the hyperhidrosis was also materially influenced. In three cases it disappeared completely.

The rapid response of these resistant cases to the ordinary therapeutic measures following the correction of the foot deformity justifies the conclusion that orthopedic corrective measures are a therapeutic adjunct in the cases of fungous infection of the feet associated with flatfoot.

Acute Interstitial Myocarditis—Maxwell and Barrett report a case of acute interstitial myocarditis in which there was an extensive infection of the skin and mucous membranes with *Staphylococcus haemolyticus*. Postmortem examination did not show any evidence of septicemia, so that if the myocarditis was related to the pyogenic infection it must have been through the absorption of bacterial toxins. The gross and microscopic appearance of the abdominal viscera supported this view. No case of acute interstitial myocarditis has ever been diagnosed before death, however, the authors believe that with the picture of progressive myocardial failure following a pyogenic infection of the skin and without septicemia, the cardiac lesion could be reasonably suspected.

Multiple Epitheliomas and Pigmentary Dermatoses—Hopkins and Van Studdiford describe an instance of cutaneous epitheliomas of the face in a Negro, in which the clinical and histopathologic diagnosis was that of multiple squamous cell epitheliomas. A more generalized dermatosis is diagnosed as arsenical pigmentation on the evidence of the histopathologic picture and on the presence in the skin of arsenic trisulphide crystals. The distribution of the lesions, however, was in conformity with that of *xeroderma pigmentosum*. The epitheliomas of the face were a sequence of the arsenical pigmentation in this region and, it is assumed, were caused by deposits of arsenic. The fact that arsenic presumably carried by the blood stream to the skin and there deposited resulted in this case in the development of epitheliomas suggests the possibility that Negro racial immunity to cutaneous epitheliomas is due to protection from external and not from internal sources of irritation and that the major part played by the pigment of the black skin, so far as immunity against epitheliomas is concerned, must be protection against actinic rays and similar natural external sources of irritation.

Treatment of Dementia Paralytica with Typhoid H Antigen Vaccine—Schnitker treated twenty-five dementia paralytica patients physically unsuitable for treatment with malaria, whole typhoid vaccine or diathermy with typhoid H antigen (flagellar) vaccine alone and in combination with tryparsamide. The symptomatic and serologic improvement obtained by this method compares favorably with results obtained with other forms of fever therapy. Typhoid H antigen vaccine is indicated for persons who cannot withstand the rigors of other forms of therapy because (1) although the hyperpyrexia equals that obtained with whole typhoid vaccine the concomitant illness is far less severe, (2) it does not involve superimposing a second (and perhaps lethal) infection on an already existing one, as with malaria, (3) it does not involve the risk of burns and renal damage, as with diathermy, (4) its contraindications are severe cardiorenal disease, active pulmonary disease, severe cachexia and acute infection with a rapid sedimentation rate, (5) its administration and control are simple and its use in the hands of the general practitioner both in the hospital and in the home, is safe and (6) it has not, in

the author's experience, been associated with complications or sequelae. More attention should be directed to the total hours of fever produced in a patient than to a definite number of paroxysms. Tryparsamide can be given at the height of the fever with better clinical results and no increase in the dangers of complications.

Meckel's Diverticulum—Schullinger and Stout report a case of Meckel's diverticulum in which the mucosal surface near the tip was the site of a nonulcerated pedunculated adenoma composed of gastric and duodenal glands. The case emphasizes that extremely severe acute symptoms including abdominal pain and bleeding from the rectum, unmixing with mucus, may occur

in persons with Meckel's diverticulum without any evidence of invagination intussusception or ulceration. Heterotopic tissue was present in the diverticulum, but the source of the bleeding could not be determined either at operation or microscopically. It is reasonable to suppose that it must have come from the diverticulum, since hemorrhage did not recur after its removal. Because their patient, together with other reported cases exhibited symptoms similar to those recorded for the group who had bleeding associated with ulcer of a Meckel's diverticulum the authors believe that the latter condition cannot be considered a clinical entity. The indication is to remove the diverticulum even though it may appear harmless because the mortality is high after perforation or after acute pathologic processes set in. A person with a lesion of Meckel's diverticulum, especially if the lesion is a bleeding peptic ulcer may pass from a state of relatively good health to one of acute illness collapse and shock with amazing rapidity. Sudden severe pain in the lower part of the abdomen with rigidity, signs of diffusing peritonitis, fever and leukocytosis especially in children should lead one to suspect a perforated Meckel's diverticulum. Cryptic intestinal bleeding should always constrain one to suspect a Meckel's diverticulum as a possible source.

Anaerobic Organisms in Peritonitis Due to Liver Autolysis—Trusler and Reeves attempted to ascertain whether toxic strains of *Clostridium welchii* regularly inhabit the liver of healthy dogs and if the same organisms are present and cause death in bodily autolysis of liver. They studied the livers of sixteen normal healthy dogs and the muscle tissue from six dogs. Toxic strains of *C. welchii* were not found. The livers of the sixteen dogs contained a strict anaerobic bacillus thermophilic in its reaction to heat, a member of the genus *Clostridium* and of the metabolic group of non sucrose-fermenting, putrefactive, gas-forming organisms. The muscles of five normal healthy dogs contained a less strict anaerobic bacillus, not thermophilic in heat reaction a member of the genus *Clostridium* and of the metabolic group of sucrose-fermenting putrefactive, gas-forming organisms. A sample of muscle from one dog was sterile. The organisms occupying the livers and muscles of the dogs studied do not produce an exotoxin. They are in this respect, nonpathogenic. These organisms are all large gram positive bacilli. Their morphology and gas production easily confuse them with pathogenic forms. On two occasions when large masses of liver were incubated, organisms were found which closely resembled *C. welchii* in morphology. They differ in sugar fermentation form no exotoxin and were not pathogenic when injected in young broth cultures intramuscularly into guinea-pigs. Livers of fetal dogs are uniformly sterile.

Removal of Tumors of Third Ventricle—Masson removed successfully the tumors of the third ventricle in two cases. Both were in the anterior part of the third ventricle. In retrospect it appears to him that a much smaller bone flap would answer, for only a limited extent of the dural exposure was used in each instance. It does not matter therefore, how wide a dural exposure is provided since the tumor and its attachment to the third ventricle are just as deeply situated and cannot be drawn to the surface until freed. It is imperative that one work carefully at a distance. Irrespective of the size of the craniotomy one finds oneself working at a distance from the root and one has to depend on careful technic to be successful. If the lesion is totally extirpated a decompression is not required since the cause of the increased intracranial pressure has been removed.

Supraperiosteal and Subcostal Pneumonolysis—Alexander describes the technic of supraperiosteal and subcostal pneumonolysis with a filling of the pectoral muscles. The procedure is chiefly indicated for cavernous tuberculous or non-tuberculous lesions that lie between the clavicle and the level of the third rib anteriorly. The operation is performed under gas anesthesia with the patient in about a 15 degree Trendelenburg position. One was a man of 53 having arteriosclerosis with a foul nontuberculous abscess. After operation improvement was rapid at first then gradual three years after operation the patient was apparently cured. On three of the six

tuberculous patients the operation was done successfully as preliminary to thoracoplasty in order to displace a large cavity backward so that the thoracoplasty would have a better chance of completely closing it. One of the three remaining patients died as a result of the operation. Another patient for whom the operation was used independently was 56 years old and had arteriosclerosis intestinal tuberculosis and an anal fistula dyspnea hemoptyses, fever and a rapid pulse. When discharged from the sanatorium seven months after operation, he had gained 20 pounds (9 Kg), and a roentgenogram showed great clearing in the tuberculous infiltration and apparent disappearance of the cavity. The sputum was reduced to 70 cc daily and was still positive for tubercle bacilli. The last patient, 24 years old had had pulmonary tuberculosis for seven years. Thirteen months after operation he had gained 35 pounds (15.9 Kg), his sputum was reduced to 10 cc daily and was repeatedly negative for tubercle bacilli during the last four months.

Bilirubin Formation and the Reticulo-Endothelial System—Gotthieb made a comparative study of the Kupffer cells with other cells of the reticulo-endothelial system in rabbits guinea pigs and rats. The rabbits received daily injections of 10 cc of a 2.5 per cent lithium carmine suspension for from five to ten consecutive days the guinea-pigs 5 cc for

five days and the rats from 1 to 2 cc for from three to five days. All the injections were given intraperitoneally. The animals were killed by coal gas and sections made of the organs. With the exception of the bone marrow, which was fixed in Zenker's fluid, the tissues were hardened in formaldehyde, passed through alcohol and toluene, and petrolatum sections were cut. The carmine sections were slightly counterstained with hematoxylin and the trypan blue sections with bismarck brown. The author agrees with Zimmermann and others that the Kupffer cells are true independent cells which are suspended in the liver in such a manner that they are well surrounded by the blood stream. They are nucleated cells attached to the wall by protoplasmic processes only, functionally, they are able to store intravitaly like all the other cells of the reticulo-endothelial system. Even if the existence of the reticulo-endothelial system as such should be called in question, there remains the fact that a number of groups of cells of mesodermal origin are capable of storing carmine intravitaly. It does not appear reasonable to exclude the Kupffer cells alone and deny their cell nature, as it is assumed by Pfuhl and his followers. The proliferation of Kupffer cells after splenectomy is another fact of importance. One could hardly expect mere thickenings of the endothelial wall to proliferate on account of an increased functional demand.

Diabetic Coma Refractory to Insulin—Jameson reports the case of a woman of 58 having diabetes who was admitted to the hospital in deep coma after an abstinence from food and insulin for eighteen hours. There had been repeated vomiting during this period. Three years before she had been under the author's care, having then suffered for three years from diabetes. She left the hospital on a low fat, high carbohydrate maintenance diet, with 45 units of insulin daily. She had not reported in the interval, but her husband said that she had remained in good health as long as she adhered to her diet and insulin. A trip to the city resulted in a visit to an irregular practitioner who said he could do nothing for her until she stopped taking insulin. This resulted in coma. There was little change in the blood sugar throughout the duration of the coma. The carbon dioxide combining power rose from 11 volumes per cent to 37.5, but even with continued excessive dosage of insulin it fell again. The urine was never free of sugar or ketone bodies. No evidence of sepsis was found at necropsy. In fourteen hours 1,140 units of insulin was given. Histologic sections of the pancreas showed marked diminution in the number of islands of Langerhans. Those present were small and the cells atrophic in appearance. The case seems to belong to the fourth group as outlined by Thannhauser and Fuld.

Reducing Supracondylar Fractures of the Humerus—Macnab uses the following method in reducing supracondylar fractures of the humerus. The arm is grasped by the operator with both hands, the thumbs being placed vertically on the posterior surface at the line of fracture. The forearm under moderate extension is hyperextended by the assistant over the thumbs of the operator, at the same time being moderately abducted. The operator gradually works the lower fragments down until the fracture lines approximate as nearly as possible. The assistant then, increasing the extension, flexes the forearm, carrying it through an arc of a circle that brings it well inside the shoulder, the operator in the meantime retaining the alignment with his thumbs. The radial artery is palpated to ascertain the presence of a pulse. A small piece of cotton is placed in the angle of the elbow and adhesive straps are brought around the arm and forearm to hold a hyperflexed position. A roentgenogram is taken immediately after reduction. If the fracture is found to be satisfactorily reduced, the arm is held in a sling and the hand fastened to a collar around the neck. At the end of two weeks the straps are cut and a little passive motion is started. Radiant heat and gentle massage are advised at this time. The straps are reapplied for another week. At the end of three weeks the dressing is removed and the patient is encouraged to move the arm voluntarily. When the patient is not exercising under supervision the hand is fastened to the collar. At the end of the fourth week, weights may be carried and more vigorous methods adopted to secure extension of the forearm.

Hemisection of Cochlear Branch of Auditory Nerve—Dandy cites a case in which the audiogram thirteen days after hemisection of the sensory root of the fifth nerve showed that all the tones up to 6,144 were almost exactly the same as before the operation, only the higher tones, 8,192 and 12,288, were lost. The highest tone, 16,384, was absent both before and after the operation. An audiogram made the next day showed identical results. The immediate result, therefore, following section of one half, at least, of the cochlear branch of the acoustic nerve is loss of only two of the very high tones. This observation is seemingly in complete harmony with the results of partial division of the trigeminal and optic nerves.

Digestion of Beef Proteins in the Human Stomach—Maltby studied the digestion of protein in the human stomach and reports the quantitative fractional analyses of the gastric digests. Considerable peptic hydrolysis of meat can occur in the stomach in a relatively short time. There is a wide variation in the extent of hydrolysis of beef muscle protein in the normal individual. This variation occurs not only in different normal subjects but also in the same person. Subjects having pernicious anemia accomplish little or no gastric digestion of meat. No pepsin was demonstrated in the gastric contents of achlorhydric cases without pernicious anemia or of patients suffering from pernicious anemia. Achlorhydric cases without pernicious anemia showed a small amount of gastric digestion. A somewhat smaller amount was found in pernicious anemia cases. Pepsin secretion and acid secretion appeared to parallel each other in amount. The pH of the gastric contents in persons having apparently normal gastro intestinal tracts ranges from 1.23 to 6.63. No pernicious anemia patients had a pH below 5.75 for the gastric contents. The titratable acidity ranged from 151 cc of tenth normal acid per hundred cubic centimeters of gastric contents to zero, varying in individual cases. Bile was present in the gastric contents in measurable amounts in about 25 per cent of the normal subjects tested and in 18 per cent of the subjects with pernicious anemia. These conclusions are based on observations of gastric digestion of meals consisting only of meat.

Cutaneous Reactions in Diagnosis of Undulant Fever—Goldstein tested the endermic reactions of 253 patients by the intradermal injection of whole *Alcaligenes abortus* organisms killed by heat. Twenty-six or 10.3 per cent, of the group reacted positively. The reactions of ninety-two patients were similarly tested with *Alcaligenes abortus* organisms which had been extracted with alcohol and ether. Nine, or 9.6 per cent, gave positive reactions to the "fat-free" antigen. The "fat-free" antigen produced fewer general reactions and less severe local reactions than did the "heat-killed" vaccine. It did not materially increase the antiabortus agglutinin titer of the serum. The author recommends the endermic reaction for use as a supplementary procedure for the diagnosis of undulant fever, not only in those patients who have an unexplained fever but also in those afebrile persons without antiabortus agglutinins in their serum who may be suspected of having symptoms referable to an *Alcaligenes* infection.

Kidney Function and Blood Pressure—Lassen and Husfeldt followed the course of the glomerular filtration ("creatinine clearance," Rehberg) in four young men, cardio-renal healthy, while they were under spinal anesthesia, during which the fall of blood pressure was not compensated. They observed that 1 During the rather considerable fall of blood pressure which appeared when the effect of the anesthesia was at its height, the glomerular filtration decreased markedly and to a degree that corresponded fairly well with the fall of blood pressure. 2 At the same time, the concentration index increased significantly and remained high, or rose even further during the subsequent gradual rise of blood pressure. Thus the tubular function was normal, as far as the reabsorption of water is concerned or even hypernormal at the same time that the effect of the spinal anesthesia was at its height and the filtration was lowered. 3 During the fall of blood pressure there was an enormous decrease in the volume of urine, partly on account of considerable reabsorption of water in the tubules, partly on account of the lowered filtration in the glomeruli. In three of the authors' control experiments the course of the glomerular filtration was followed under spinal anesthesia during which the fall of the blood pressure was counteracted by injection of ephedrine or ephedrine and caffeine. Ephedrine (or ephedrine and caffeine) was able under optimally effective spinal anesthesia to maintain at the same time both a normal blood pressure and a normal glomerular function. The function of the tubules was not affected by this. The relation that was found between the blood pressure and the kidney function under the experimental conditions can be readily explained in accordance with the filtration reabsorption theory.

Rift Valley Fever—Schwenker and Rivers report a case of laboratory infection of Rift Valley fever which terminated in death. The course of the disease was characteristic with the exception that it was complicated by thrombophlebitis, the patient dying from a pulmonary embolus. The phlebitis which

appeared during convalescence, was an unexpected complication. It seems probable that should the number of cases of Rift Valley fever increase, phlebitis will again be seen as a complication in a certain proportion of them.

 *Narcosustained Therapy with Diallylbarbituric Acid in Psychiatry A B Magnus Chicago—p 286
 A Few Remarks on Brain Function G Vercellini Fresno Calif—p 301

Lecithin in Treatment of Multiple Sclerosis—Weinberg treated twelve cases of multiple sclerosis with intraspinal injections of lecithin in accordance with the method of Minnea and Dragomir. Ten of the cases have been carefully studied

before and after treatment. Nine of the ten showed greater or lesser improvement. Among these were several severe cases. The method is harmless, though rather severe on the patients in certain respects. In its entirety it consists of intraspinal lecithin injections, the administration of cod liver oil over long periods of time, and the administration of quinine hydrochloride. The theoretical grounds for the success of the treatment from the author's standpoint are that lecithin neutralizes the lipolytic substance present in the spinal fluid, and he believes that the results are sufficiently good to justify its further use.

Sustained Sleep Therapy in Psychiatry—Magnus presents a study of thirty-eight cases of mental disorder in which eighty-five treatments of sustained sleep therapy were given for a period of nearly four years. He found that sustained sleep therapy is a valuable method in manic depressive psychosis, in certain types of schizophrenia and in psychoneurosis. Of the other groups, too few cases were available. The method that he employed was a modification of the one used in the Burgholzi clinic, consisting of administering diallylbarbituric acid rectally for a period of about ten days. In the prenarcoctic stage, diallylbarbituric acid is given by mouth and occasionally intramuscularly when indicated. During the narcoctic stage, morphine-scopolamine is given on the third day of the treatment and continued thereafter now and then, to lessen the possibilities of acquiring a tolerance to diallylbarbituric acid. Narcosustained therapy is not without danger. The dangers are lessened by carefully eliminating contraindications, by maintaining a light state of sleep and by employing a specially trained nursing personnel. The quality of sleep has no bearing on the ultimate clinical outcome, lightly narcotized patients with frequent periods of wakefulness having shown equally good results. In the postnarcoctic stage lasting for three days or more the patient is conscious but his memory for recent events remains clouded and retention is poor. Situational conflicts are often clearly revealed and confabulations are not infrequent. Most patients show beneficial effects in some manner. Long standing deteriorated cases respond slightly, if at all. Among the improved, some are able to resume their former occupations, at least in part, outside the institution. Involuntal cases responded poorly.

Iron Metabolism—Reznikoff and his associates observed that a normal subject stored iron when placed on an intake of 26 mg daily and was in balance when on an intake of 10 mg before any therapy was started. A parenteral liver extract, which is potent in causing a remission in pernicious anemia, appeared to cause a retention of iron when the subject was taking 10 mg, and an increase in iron storage when he was taking 17 mg. When he was put on a high iron intake approximately 80 mg, the administration of parenteral liver extract was followed by a marked increase of iron excretion. Copper sulphate seemed to decrease the iron loss. The administration of a liver fraction supposedly potent in secondary anemia was followed by a retention of iron above that obtained when iron in quantities present in the liver fraction alone was given. The administration of massive doses of iron (2 Gm) gave a marked retention of iron. During a remission stage a polycythemic patient was on a slightly positive iron balance when his intake varied from 14 to 18 mg. Even with a decrease of 50 per cent of his blood following phenylhydrazine no marked increase of iron excretion was obtained. This suggests that the great bulk of iron so liberated is stored in the body. Iron excretion in the urine is little and remarkably constant and cannot be increased by any method tried in these experiments. The amount of iron excreted per gram of dried stool is remarkably constant except when large amounts of iron are given. The red blood cell count and hemoglobin values had only an indirect relationship to iron intake and therapy in the normal or polycythemic subject because of the intermediation of the iron storage depots.

Achondroplasia in a Twin—Benjamin and Brookner present a case of achondroplasia occurring in a twin. It is difficult sometimes in the early months of infancy especially in an obese child to make a diagnosis of micromelia the characteristic feature of achondroplasia. In the authors case the child was seen at 10 months and was presented at the clinic with its normal twin. The general puffed or bloated appearance of the child with its unusually large head made one think of cretinism. The short extremities the disproportion between the trunk and the extremities and the roentgen observations leave no doubt as to the diagnosis of achondroplasia.

Diagnostic Tuberculin Reaction—Greengard and Nichaman observed that the intradermal reaction is best suited for routine hospital use and should supplant other methods for this purpose. The total protein tuberculin reaction (Seibert) is

extremely sensitive and will detect a higher proportion of positive reactors than will old tuberculin in doses a hundred times as great. The dermatotuberculin test, less sensitive than the intradermal test, is extremely useful because of the ease and painlessness of its application. It is well suited to routine office use. The Pirquet scarification reaction is greatly inferior to either the intradermal or dermatotuberculin test. Either of the latter is therefore preferable for routine use. In a series of 647 consecutive children a positive reaction to one or more of the tests was obtained in 185 and 111 reacted positively to all tests.

Action of Amyl Nitrite in Complete Heart Block—Gilchrist recorded the response of seven cases of complete heart block to the inhalation of amyl nitrite by continuous electrocardiograms over the period of changing blood pressure. In two subjects a remarkable increase in ventricular rate was observed, the percentage acceleration amounting to 83 and 93, respectively. By contrast the corresponding auricular gain was in the neighborhood of 30 per cent in each of these cases. Amyl nitrite did not relieve the block. In the remaining five cases, while the auricles were accelerated by various amounts of the drug the ventricular gain was slight, ranging from 15 to 185 per cent of the resting rate. Employed as a rough and ready clinical test for the elucidation of the nature of bradycardia this would imply that, while a failure to accelerate after the inhalation of amyl nitrite is in favor of complete heart block, acceleration in itself is compatible with the presence of complete dissociation. In other words, a negative response favors complete block but a positive does not exclude it. No striking alterations were observed in the form of the electrocardiographic deflections except in one case and no untoward symptoms occurred even in the two cases complicated by free aortic regurgitation.

- Diaphragmatic Hernia in Rabbit J D Bisgard Omaha—p 325

New Principle of Pulmonary Collapse—Wolfe and his associates experimented on twenty dogs to test a method on normal lungs whereby one portion of the organ was afforded vigorous compression with such reduction in size and such cirrhotic change as to render it virtually extinct by causing its pleura to thicken and shrink. The lobe was enclosed as far

as the hilus in a loosely fitting envelop of thin rubber and then was left fully inflated. The foreign body produced an intense pleural reaction, so that free fluid accumulated and the pleura in contact with the rubber became thickened and fibrous. The fluid collapsed the lobe and soon afterward underwent absorption, while the fibrous capsule of the lobe maintained and furthered the collapse by shrinking progressively. The envelop relaxed in folds about the organ. Hyperemia and fibroblastic proliferation developed in all parts of the parenchyma, and the cirrhosis progressed until all respiratory structures except the largest bronchi were replaced with scar tissue. These tubes remained intact, although collapsed. The shrinkage was so extensive as to reduce the lobe in a few months to a small, firm mass. The space so left was filled mainly by the neighboring lobes, which were hypertrophied, and otherwise by the heart, hemidiaphragm and chest wall, which were slightly displaced. The pulmonary compression obtained by this method is unique because of its independence of mediastinal stability, as well as because of its superior forcefulness. It should have special advantage when used clinically for collapsing stiff walled cavities of the lung. Also, the cirrhosis may possibly prove advantageous for limiting and healing noncavernous lesions. However, further study of the meaning of the parenchymatous changes and much technical refinement are needed before application is made to man.

Extra-Intrapleural Supraclavicular Apicolysis—Joanides and Shapiro propose a method for the collapse of adherent apical pulmonary cavities, to be used especially in cases in which there are definite contraindications for thoracoplasty. This operation may be performed independently or at one sitting when either a scalenotomy or a phrenic neurectomy is done. It does not require a larger incision than that which is necessary for a scalenus muscle section or a phrenic nerve resection. The operation is comparatively safe when one keeps in mind the important anatomic structures in this region: the carotid sheath with its contents, the transverse cervical artery, the trunk of the cervical sympathetic, the brachial plexus and the subclavian vessels.

Nephrostomy Preliminary to Nephrectomy—Gutierrez calls attention to the importance of a preliminary nephrostomy before carrying out nephrectomy in selected cases of pyonephrosis in which the condition of the patient does not warrant exposing him to the shock of the removal of the diseased organ. Nephrostomy as a preliminary drainage is not recommended in tuberculous pyonephrosis, when the kidney can be readily exposed and removed without any difficulty. The author states that irrespective of the surgical difficulties that may be encountered during the performance of a secondary nephrectomy, the final results in many instances of large and extensive pyonephrotic kidneys will justify the conservative method employed. The mortality is much lower after two-stage nephrectomy than after a hasty primary subcapsular nephrectomy. The author believes that the standardization of this surgical procedure will undoubtedly serve not only to relieve the temporary symptoms but also to bring about permanent cure in many grave cases.

Pregnancy and Syphilis—Soule reviews the problem of pregnancy and syphilis. In his clinic an attempt is made to administer as vigorous treatment as the mother will tolerate safely. Prenatal care is given by the same observers at weekly intervals through the duration of treatment, the urine is examined carefully and the blood pressure taken weekly. Each case is individualized and treatment calculated for the remain-

ing duration of pregnancy Weekly injections of 0.3 Gm of arsphenamine are given for a period of twelve weeks Concurrently, in the last three weeks of this period, 15 cc bismocymol is given intramuscularly once a week After six weeks treatment with bismocymol given once a week, another series of arsphenamine injections is begun An attempt is made during the early calculation to complete the treatment (at term) under arsphenamine or neoarsphenamine alone on the basis that the arsenical preparations are less irritating to the kidney than compounds of bismuth or mercury An "adequate" course of treatment is at least eighteen weeks A preliminary survey of his own patients reveals that at least 80 per cent of the mothers who received six or more arsphenamine or neoarsphenamine injections delivered healthy children with negative blood Wassermann reactions at 3 months of age and without any of the physical stigmas of syphilis The best results are obtained with treatment from the beginning of pregnancy and pursued throughout the gestation

New Intravenous Agent for Control of Peptic Ulcer
Butman and his associates used a combination of sodium citrate and sodium chloride buffered to the correct hydrogen ion concentration with a buffer salt in treating twenty cases of duodenal and two of gastric ulcer Triply distilled water is used and it is sterilized (after the hydrogen ion concentration has been checked by titration) under pressure It is then transferred under absolutely aseptic conditions into sterile 20 cc nonsoluble Jena glass ampules The use of an ordinary 20 cc syringe is most practical and the dosage has been graduated in the following manner first dose 10 cc and for the remaining doses the contents of a 20 cc ampule The injection may be given two or three times a week or in severe cases, every twenty four hours They feel that, following the regular course

of twenty-four injections, it is advisable to continue giving one injection every two to four weeks for a year In no case have any untoward reactions other than a pleasant tingling sensation in the tongue and lips been experienced Hemorrhage, which is a common complication of peptic ulcer, is no contraindication This therapy permits regular well balanced and well chosen meals from the onset of treatment The authors believe that the intravenous injection of the solution appears to be more effective in the treatment of peptic ulcer than the classic regimens that have been tried in the past It approaches more accurately the supposed etiology of peptic ulcer It promotes healing by (1) improving the chemical or acid base balance of the blood (2) improving both the direct and collateral circulation to the ulcer bearing area of the stomach and duodenum, thereby lessening the tendency toward capillary stasis or venofibrosis with consequent malnutrition of gastroduodenal mucosa, (3) improving the tissue resistance to digestion of the same by the gastric secretions, and (4) improving the general circulatory system throughout the body with resulting increased resistance to systemic disease The authors obtained symptomatic cure in all their patients As yet they make no positive statement as to permanent cure

Nutrient Broth in Treatment of Wounds—Speidel employed nutrient broth made up of meat extract, peptone broth, it may or may not contain dextrose as desired and it has some sodium chloride and sodium hydroxide to bring it up to a nonirritating pH of 7, with the addition of a weak solution of procaine hydrochloride as required It is applied in the form of a saturated compress, a gauze wick drain, by infiltration into the margins and base of a wound and by irrigation The author cites the following cases in which this method of treatment was applied 1 A man having three suppurating wounds on the right elbow, one being three-fourths inch in diameter, another one-half inch in diameter and a third one-eighth inch in depth, that had been variously treated with indifferent results for four weeks following injury and infection Two days subsequent to injection with nutrient broth and application of a small compress under cellophane they were healed 2 An extensive and dissecting fistula-in ano in which, after complete dissection of the tract, the usual method of leaving it packed and open to granulate was replaced by infiltration with broth and primary closure This resulted in primary union 3 A patient having a diffuse right-sided, suppurative, perforative appendicitis, whose wound was closed without drainage after removal of the appendix and the injection intraperitoneally of 400 cc of broth Convalescence was strikingly normal in regard to the peritoneum The wound, however, healed with suppuration, the explanation being that broth had not been injected into the walls of the abdominal incision The author concludes that there have been many similar instances, for example carbuncles, furuncles and indolent ulcers, but that the foregoing cases serve to indicate the general utility of the treatment

Malaria Treatment of Dementia Paralytica—Freeman and his associates present the results of 195 out of a total of 205 dementia paralytica patients whose progress was followed for a period of from five to eleven years after they received malarial treatment. Of these, 31 per cent were discharged from the hospital, 39 per cent remained hospitalized and 30 per cent

are known to be dead. The remissions obtained show indications of being permanent and the percentage of recoveries has not declined with the passage of years. Failures in malarial therapy are chargeable largely to delay in its administration and to restriction of the number of paroxysms. Persistently positive serologic responses after three years indicate the probability of failure, but negative responses are often found in deteriorated patients.

Some Developments in Renal Surgery—Lowsley points out that animal experimentation and clinical experience based on observation at the operating table, functional tests after operations, and pyelographic and microscopic studies prove that (1) hemostasis is most satisfactorily accomplished by tying ribbon gut round kidneys subjected to nephrotomy, (2) there is perfect healing and apposition of the parts, (3) there is the slightest amount of distortion of the kidney pelvis and (4) there is little if any diminution of function in kidneys thus treated. Nephropexy accomplished by the use of chronic ribbon gut as described by the author is a perfectly satisfactory method of operation in suitable cases. Experimental studies and clinical observation of rupture of the kidney convince the author that 1 Every patient having renal traumatism of sufficient severity to cause hematuria or pain in the kidney should be hospitalized. 2 Examination should be instituted within twenty-four hours if the hematuria continues. 3 Rarely does renal traumatism cause primary rupture of the fibrous capsule, although this structure may be digested by the ferments released by traumatism to the cortical substance resulting in perinephritis, infiltration of urine and pus and in many cases complete destruction of the kidney and menace to the life of the patient. 4 The operation of choice in rupture of the kidney is control of hemorrhage and repair of the lacerated portion of the cortex by means of ribbon gut properly applied. Drainage is accomplished by means of soft rubber tubes. Fat is much superior to muscle or any other bodily tissue as an aid to the control of hemorrhage of the cortex of the kidney.

Relaxation of Pelvic Joints in Pregnancy—Abramson and his associates believe that relaxation of the pelvic joints and particularly of the symphysis pubis is a normal accompaniment of pregnancy. Relaxation of the symphysis begins in the first half of pregnancy, progresses but slightly in the last three months, and is but little affected by parturition. Retrogression begins immediately following delivery and is usually complete by the end of from three to five months. The process of relaxation is physiologic and is probably the result of hormone activity. Abnormal separation of the symphysis pubis occurs in about 25 per cent and probably results simply from an exaggeration of the normal physiologic process, only exceptionally does trauma play any part. Symphyseal relaxation is accompanied by an increase of pubic mobility and is frequently associated with characteristic symptoms resulting from instability of the pelvic joints. Treatment is indicated to relieve symptoms and

to prevent the development of a condition of chronic relaxation of the pelvic joints, which is frequently responsible for a great deal of later discomfort among women who have borne children. The key to the situation lies in the prompt recognition of abnormal separation of the symphysis when present, and in order to detect this the obstetrician should include the symphysis pubis in his regular routine of examination of the pregnant patient both before and at the time of delivery.

Treatment for Fractures of Tibia and Fibula—Anderson presents a method of treating fractures of the tibia and fibula with an automatic splint in which fragments are automatically aligned and immobilized. The preparation of the leg includes shaving and cleansing with soap and water, and then sterilization with ether and iodine, followed by alcohol if the iodine is strong. An injection of from 5 to 20 cc of a 2 per cent solution of procaine hydrochloride is made into the skin and down into the periosteum on each side of the tibia at both sites of transfixion, while from 20 to 60 cc is injected into the hematoma and round the end of each fragment. The distal pin is put straight through the center of the tibia at a point two fingerbreadths superior to the tip of the internal malleolus. Recently the author has changed the site of the superior insertion to transfix the condyles of the tibia at their widest part midway between the anterior and posterior surfaces, just distal to the knee joint. Without incising of the skin or preliminary drilling of the bone, each stainless steel Steinmann pin is forced through by rotary hand pressure alone. Sterile dry dressings, about 3 inches square, spiked over each pin-end, safeguard infection, they are held close to the wound by a bandage of nonsterile sheet wadding. By grasping the foot and pulling on it the assistant raises the leg while the splint is placed beneath and the pins are clamped to their respective horseshoes. The foot and ankle are padded with sheet wadding special attention being given to protection of the heel. All malposition is now controllable, traction and rotation are adjusted, angulation is corrected and the adjustable foot rest is set. When the reduction is complete it is roentgenographically checked. Separation of fragments due to overtraction must be assiduously avoided because, notwithstanding perfect alignment, usually no result can be considered satisfactory without end-to-end pressure contact. Immobilization of satisfactory reduction is completed by the application of a cast, which firmly incorporates the pins and generally extends from midtigh downward over the foot plate to slightly beyond the toes. The sole of the foot should be reinforced with a 4 inch plaster bandage. When the plaster is set, the pin clamps are loosened and the leg in its cast is lifted free from the horseshoes and from the foot plate. Ordinary corks are placed on the ends of the pins which are then covered and fastened to the cast by a plaster bandage. A window cut over the patella serves for subsequent mobilization of the cap, allowing freedom of movement.

Two Stage Operation for Fistula-in-Ano—Allen and Haskell describe a modification of Pennington's two stage seton method for anorectal fistulas. They obtained good union of the ends of the muscles without deformity and good function of the sphincters with their modified method in 119 cases. The severity of the fistulous process varied widely. Twenty-four were of the "horseshoe type," bilateral tracts communicating either anteriorly or posteriorly to the anal canal. One patient presented fourteen external openings. Sixty-two had two or more external openings. Eight gave both clinical and histologic evidence of tuberculous infection. In one case in which the blood Wassermann reaction was positive histologic examination of the tissue strongly suggested a syphilitic process. In another, the fistulous tract communicated with a postanal dermoid cyst.

Operation for Traumatic Arteriovenous Fistula—Jackson overcame the danger of hemorrhage and the use of a local anesthetic when completely excising a traumatic femoral arteriovenous fistula of a duration of six years by administering a low spinal anesthesia, completely exsanguinating the limb by applying an Esmarch bandage from the foot to the groin, placing Wyeth pins as for amputation at the hip applying a tourniquet proximal to the Wyeth pins, and removing the Esmarch bandage. The institution of these measures not only greatly facilitated the technical performance of the operation, which was carried out in a perfectly dry field of uninfiltated tissues, but also minimized the time required for its performance. The authors patient sought aid because of dyspnea on exertion, due to a dilated and hypertrophied heart ensuing from the establishment of a double circulatory system incident to the establishment of the fistula. The author believes that the decision as to what particular operative procedure—endoaneurysmorrhaphy, transvenous suture or radical excision—should be made only at the time of operation by direct inspection of the lesion. No operation should be undertaken until the collateral circulation test of Matas is positive. The development of a traumatic arteriovenous fistula of the femoral vessels should be prevented at least to some extent by the recognition on the part of the general practitioner and surgeon that every penetrating injury in the vicinity of the femoral vessels which is followed by swelling and ecchymosis of the thigh deserves immediate hospital and competent surgical attention. He suggests that by the use of preparatory and postoperative blood transfusions such patients could be operated on soon after the injury, under spinal anesthesia, and that, by the utilization of Wyeth pins and a tourniquet at the hip ready access to and repair of the incisional injury to the vessels could be reasonably assured.

Changes in Esterase and Fat Content of Serum Induced by Cancer—Green observed that during the growth of the rat Jensen sarcoma the esterase content of the serum falls progressively, ultimately reaching a low level. The esterase content of the liver, lung and kidney is much diminished. The phosphatase content of the serum falls, but the average fall is less than half that of the esterase. In rats resistant to inoculation of the Jensen sarcoma the esterase content of the serum tends to rise. The fatty acid content of the serum rises in many and possibly in all rats during the growth of the Jensen sarcoma. It may reach a maximal level approaching 2 per cent, and then falls during the terminal stages of tumor growth. There is an associated rise in the cholesterol, but of a much less degree. In rat epitheliomas of mice and in localized human carcinomas the serum esterase content ranges round normal, with a tendency to rise slightly. Evidence was obtained that the application of tar or the inoculation of tar or 1,2,5,6-dibenzanthracene produces a rise in the esterase content of the serum of rabbits in a proportion of cases. The author discusses the possible significance of these observations.

Vulvoperineorrhaphy—Robinson believes that since it is difficult to obtain and impossible to preserve an aseptic field of operation in the presence of an open intestine a 1:80 phenol lotion should be employed as an antiseptic throughout the operation. A deliberate attempt should be made to eliminate all actual and potential spaces in the new perineum because a blood-tight wound reduces the risk of infection and promotes good healing. Special effort should be made to secure hemostasis. The date of operation should be arranged with due regard to the menstrual cycle so as to avoid, as far as possible, the onset of menstruation during early convalescence. In forty-

eight of fifty consecutive operations the author obtained a satisfactory functional result, as shown by the capacity of the patient to retain flatus. The wound in two patients did not heal satisfactorily, both patients had been operated on elsewhere and in one patient, suffering from lupus of the nose, there was a marked suggestion of local tubercle.

Study of Hypothyroidism—Mudahar and his associates describe a rare case of thyroid deficiency in a woman giving rise, in addition to the other symptoms of hypothyroidism to repeated abortions (but going to term when put on 0.032 Gm. of desiccated thyroid three times a day), to spontaneous flow of milk and to vesical troubles in the baby. Experimentally, it has been shown that the milk of the hypothyroid woman contains a substance capable of inducing contractions of a guinea pig's uterus at a period of lactation when the milk of normal women does not show evidence of its presence. This substance has been found to be identical with solution of pituitary. This substance is also found in normal women till a few days after delivery, probably to help involution of the uterus. The authors discuss the probability of hypothyroidism being one of the causes of frequent abortion, and the effect of solution of pituitary on the volume of the bladder and its contraction.

Artificial Production of Menstruation with Ovarian Hormones—During the last year Loeser has treated five cases of primary amenorrhea in which he tried not only to prove histologically the development of menstrual endometrium but to produce menstrual bleeding as well. In three out of these five cases he succeeded in producing normal menstruation with doses of 300,000 mouse units of a preparation of follicular hormone, followed by injections of a luteum hormone. The menstruation was normal, in the sense that the mucous membrane of the uterus curetted on the second or third day of menstruation showed all the distinct histologic indications of an efficiently functioning endometrium on the twenty-eighth day of the menstrual cycle. These women, who were aged respectively 25, 30 and 38 years had previously never menstruated and had not had any genital bleeding. The uteri of the three patients were hardly palpable and as a result of the treatment the uterus in each case increased in length to 5 and 7 cm respectively. On the first and seventh day, 1 cc of the follicular hormone containing 100,000 mouse units was given intramuscularly. On the fourteenth day another injection of 1 cc (50,000 units) was given, on the nineteenth day 1 cc (50,000 units), and from the twenty-second to the twenty-sixth day (inclusive) 1 cc of corpus luteum hormone (10 rabbit units) was given. On the twenty-eighth day menstruation ensued. It is possible, however, by administering stronger doses, and more quickly, to produce menstruation a few days earlier. The treatment not only resulted in menstruation, but also the feminine attributes of the patients, heretofore not strongly marked, were changed physically and psychically. A positive result could not be attained in two cases. Curettings revealed tuberculosis in one, the other one showed that the mucous membrane of the uterus was entirely absent.

Method of Controlling a Valvular Pneumothorax—According to Boland, if a spontaneous pneumothorax occurs air should be aspirated if there is distress, especially if it is progressive. If the recurrence of the symptoms or rising manometer pressure shows that the perforation is a valvular one, a blunt pneumothorax needle should be left in with a rubber tube attached to it, and inserted with its end just submerged in an open bottle. If this treatment does not relieve the patient and there are any signs of anoxemia, a negative pressure should be produced in the aspirating bottle without delay. A small self retaining catheter inserted between the ribs with a trocar might be preferable if the patient's condition permits, but the needle is quite sufficient is more likely to be at hand at times of emergency, and is less likely to introduce sepsis from without. The author presents a case that illustrates the necessity of controlling the treatment with a manometer, and this is always at hand in the artificial pneumothorax apparatus. This method of treatment may be disputed in that the maintenance of the negative pressure means that the perforation will remain patent and will not heal. This might be valid if it were not of primary importance to tide the patient over the effects of the pulmonary disaster. When the patient's life is saved and he has been allowed time to recover from the effects of the initial anoxemia, one can think with deliberation of the methods to be adopted to heal the original perforation. It should not be the aim to produce low negative pressures, only such a pressure as will produce complete relief should be established and if this is done the perforation which is of necessity a small one, will soon heal over.

Right-Sided Inversion of the Duodenum—Weinren discusses eleven cases of right-sided inversion of the duodenum. Four of the patients were women, ranging in age from 40 to 70. All of these were asthenic and three of them gave a history of recurrent attacks of diarrhea. One had gallstones. The other were men, ranging in age from 26 to 54. Their habitus varied more than that of the women, one of them being 6 feet 2 inches (188 cm) in height. The others however were of the short hyposthenic type. Two of them complained of attacks of diarrhea. All the patients gave histories of dyspepsia which had persisted for considerable periods and in two cases the history was suggestive of duodenal ulcer. In the one patient operated on there was no sign of any ulcer nor was there any sign of any

ulcer roentgenographically. The existence of the duodenal abnormality was confirmed at the operation. Two of the patients had had the appendix removed, and in another three the appendix appeared to be pathologic roentgenographically. It is doubtful whether the condition could be diagnosed with certainty clinically. Roentgenographically it will be missed unless the duodenum is traced to the duodenojejunal junction. The appearances once seen on the screen cannot be mistaken. The inverted duodenum may return to normal when the patient is put into the supine or prone positions. A complete examination of the full length of the duodenum during the course of barium meal examination would doubtless reveal many more of these cases. The normal duodenum is divided into four parts: superior, descending, horizontal and ascending. In the case of an inverted duodenum the stomach is generally farther to the left of the spine than usual, and the cap occupies a more transverse position. At the inferior flexure the third part, instead of going to the left of the second part, turns up to the right of the second part and goes on to join or form the duodenojejunal junction, which likewise may be situated abnormally.

Dry Air for Removal of Fluid from Bronchioles—Rudolf administered dry air to patients in whom signs of excessive pulmonary moisture could be found. Air was given in preference to oxygen, as it is the natural gas to which the body mechanism is adapted. He points out that, although the funnel method of administering dry air is more comfortable for the patient than the catheter method it should be used only when the catheter method is impracticable, as the air is likely to absorb moisture in passing through the mouth. The quantity of dry air required for each patient is, at present, indefinite, although the author has used a total quantity of more than 400 cubic feet for one patient. His results indicate that dry air is capable of removing signs of fluid from the bronchioles and alveoli. This action reduces the pressure in the lungs and thus relieves the cardiac musculature. The dry air does not, however, prevent further fluid from passing into the air passages after the termination of the treatment. The treatment can be of permanent benefit only by giving the cardiac muscle periods of comparative rest in which to recuperate. In consequence, dry air should be administered frequently over a prolonged period perhaps of days or weeks. The duration of each administration should be some hours, and at least one tenth cubic foot of dry air per minute should be given.

New Method of Local Anesthesia for Abdominal Operations—Bankoff employs the following procedure in abdominal surgery. The patient is prepared in the usual way and one hour before the operation an injection of one-fourth grain (0.016 Gm) of morphine and $\frac{1}{1000}$ gram (0.00065 Gm) of scopolamine is given. The operative field is injected with a 1 per cent solution of procaine hydrochloride forming a rhomb. The injection of the fluid is made through two opposite points equidistant from the line of the incision and radiating over all the field of operation. The needle is then introduced vertically at two points on the line of incision itself, until it pierces the internal muscle fascia. At each of these points 20 cc of the fluid is injected. The fascia is not difficult to feel because it offers a resistance to the needle which gives a special sensation to the fingers. Ten minutes after this procedure is completed the field is completely insensible. When the skin and muscle have been cut and the peritoneum is exposed, instead of an opening being made the whole length of the wound a small incision is made about 2 inches long through which 200 cc of a 0.25 to 0.5 per cent solution of procaine hydrochloride is poured into the abdominal cavity. It is now necessary to wait for five or ten minutes before proceeding with the operation. After this the peritoneum is opened and the necessary operation performed. This completed, the superfluous fluid is taken from the abdominal cavity by means of swabs or a suction pump. For hysterectomy it is advisable to inject a little of the fluid on both sides of the uterus between the two folds of the large ligament. The author is of the opinion that this type of anesthesia should be adopted in all patients who, for some reason or other, cannot stand a general anesthetic. [NOTE—A method of this kind was described by Baruch in the *Zentralblatt für Chirurgie* 1921, No 23. Baruch reviewed the literature on the subject in the same journal in 1931, No 19.—ED.]

- Calcification and Circulatory Disturbances of Bone Tissue After Roentgen Irradiation B Dahl—p 471

Encephalography in Craniocerebral Traumatisms—Lippens and Dejardin state that encephalography is generally performed by the spinal route although in certain cases they did direct ventricular puncture. The patient on a fasting stomach, receives an injection of a preparation containing papaverine one hour before intervention. He is placed in a sitting position and the puncture is made between the third and fourth spinal vertebrae. The skin is anesthetized by means of ethyl chloride. A Collin needle, 9 cm in length, to which a manometer is attached is progressively pushed in until the displacement of the manometer needle indicates the presence of fluid. About 12 cc of the cerebrospinal fluid is removed and 10 cc of air filtered through absorbent cotton is insufflated by means of a syringe. This operation is repeated five or six times. The amount used varies from 50 to 60 cc. A clear encephalography necessitates a large amount of air. The cranial cavities must be completely filled. Five minutes after the intervention, roentgenograms are taken in four different positions: face down anteroposterior face and right and left profile. These indicate the form and symmetry of the ventricles whose contours have been outlined by the air. The test of lateral transit consists in making the patient lie down for fifteen minutes alternating from right to left. If Munro's hiatus is free the air leaves the lower ventricle. In case of total impermeability, the transit is not effected. This method is harmless in the diagnosis of cranial trauma and its concussion syndrome if the patient fasts if the operation is performed slowly and not too soon after the trauma and if there are no changes in the circulatory system due to advanced sclerosis. The large ventricles normally appear symmetrical according to the amount of air injected they are at an equal distance from the median line. On the median line the third ventricle lies below and parallel to them. Sometimes there is a difference in the size of the lateral ventricles. The largest size is often observed on the traumatized side. The negatives are generally made in stereoscopic exposure. Through this process the images are clearer and more demonstrative than those furnished by direct examination. In seventy-five cases presenting craniocerebral traumatism observed by the authors from one to twenty years after the accident, ventriculography offered a positive diagnostic result.

Absorbable Metallic Material in Bone Surgery—Verbrugge treated twenty-one cases presenting fractures immobilized by magnesium. Of these cases ten were fractures of the elbow in children, two Bennett fractures, one a fracture of the lower epiphysis of the forearm, one a fracture of the humeral diaphysis, one a pseudarthrosis of the clavicle, two fractures of the calcaneum, one a complicated fracture of the instep, one a pseudarthrosis of the internal malleolus, one a spiral fracture of the tibia, one a fracture of the tibial plateau and one an arthrodesis of the knee. The author found that magnesium becomes completely absorbed from the tissues. Its absorption is sufficiently slow to permit the formation of a callus. The metal is neither toxic nor irritating. It does not produce pain but, on the contrary, produces anesthesia. The patients operated on did not develop a febrile reaction. No evident reaction was observed in the soft tissues, the skin, the bone and the joints. The periosteum did not show any more reaction than in the cases in which nonabsorbable material was used and not more than is present in cases of nonoperative treatment. In the course of its resorption which begins from the time of its

introduction, the magnesium owing to its chemical transformation causes the formation of hydrogen without apparently causing unfavorable symptoms. The maximum amount of magnesium introduced was 5 Gm and this was well tolerated. The formation of a callus seems to be accelerated by the use of magnesium.

- *Nervous Symptoms of Aurotherapy Pain Anxiety and Insomnia Syndrome with Presence of Almost Generalized Fibrillations J A Chavany and A Chaignot—p 478

Nervous Symptoms of Aurotherapy—Chavany and Chaignot observed two tuberculous patients with identical nervous symptoms during treatment with gold salts. After several injections of a total dose inferior to the smallest toxic dose, the following symptoms appeared: diffuse and sharp pain, a state of anxiety, insomnia, almost generalized fibrillations and hyperhidrosis due to lesions of the nervous system. Insomnia, emaciation and slight fever are indirect symptoms. The sharp and continuous pains were especially present in the limbs and were often accompanied by painful cutaneous hyperesthesia especially through contact. The anxiety syndrome occurred toward evening and during the night and consisted in fear of death, anguish and nocturnal agitation, with a constant desire to walk. The fibrillations were rapid arrhythmic contractions of isolated fibers of the muscles of the limbs, waist and trunk to the exclusion of those of the cephalic extremity. The muscular tic is not painful, is accentuated by cold, does not disappear during sleep and is not soothed by nerve sedatives. The hyperhidrosis in the limbs indicated disturbances of the vegetative nervous system. The objective neurologic symptomatology was vague and there were no localized amyotrophic disturbances. Unaffected by various medicaments employed, these neuropsychic symptoms disappeared without leaving a trace after three months. In both cases the tuberculosis was temporarily aggravated by the appearance of the syndrome. The seat of the lesions serving as an anatomic basis for the syndrome are the cells of the spinal cord, and sensory and motor cells. The pains observed are characteristic of pains of the cellular type. Fibrillations are generally attributed to an irritative or destructive lesion of the cells of the anterior horn of the spinal cord. The author maintains that since these fibrillations began and ended with the pains and since neither paralysis nor consecutive atrophy was apparent, there was no evidence of cellular destruction.

- Aptecolysis in Pulmonary Collapse Therapy R Mariana—p 287
- Exogenous Tuberculous Reinfection Possible in Majority of Cases Only Through Pathologically Open Ways A Campani—p 294

Reticuloeytic Formula and Tuberculous Infection—While studying the behavior of reticulocytes in tuberculous infection Severi found that the reticuloeytic formula presents a shift to the left. In tuberculosis there is a constant and marked reticulocytosis. In an attempt to determine the normal reticuloeytic formula the author studied ten normal and healthy persons of both sexes. The values observed varied from a minimum of 18 per thousand to a maximum of 14 per thousand and the average value being 108 per thousand, a comparatively higher proportion than that obtained by other authors. If in tuberculous diseases the diminution of the erythrocytes is proportional to the evolution of the disease process and the anemia is only to a slight degree secondary, important deductions may be made from the reticulocytes. The author studied the reticuloeytic formula of twenty tuberculous patients and found that there was a constant increase from a minimum of 16 per thousand to a maximum of 18 per thousand. In the reticuloeytic formula there was the usual progression of values with a predominance of the granulocytes, but the proportion between the values of the filamentous forms and the granular forms which go from a minimum of 2 per cent to a maximum of 21 per cent with a medium value of 8.5 per cent presented a marked diminution.

Keloid Scar Formation in Pulmonary Tuberculosis—Molins made a study of six cases of keloid appearing in the course of pulmonary tuberculosis on the operative scar of phrenicectomy. The keloid growth in these cases was made up essentially of connective tissue rich in capillaries, it also presented abundant cellular elements which later on became fully functioning fibrocytes. Thus the histologic structure of the keloid tissue is different from the common sclerosed cicatricial tissue poor in cells and with few capillaries. There was a hypercalcemia of the keloid tissue probably attributable to hyperfunction of the parathyroids. Of six patients affected with keloid, four presented unilateral pulmonary lesions and two small contralateral lesions. In four the disease dated from ten to sixteen months before operation and there were symptoms of fever, copious expectoration, profuse sweating and general decline in the condition of the patients. The other two who were ill seven and nine months respectively, showed an analogous symptomatology. A regional skin reaction to tuberculin in the scar area gave positive results in these cases, whereas in nineteen cases of tuberculosis not showing keloid scar formations allergic manifestations were not demonstrable. The increase in reticulocytes was thought to be an indication of alterations of the erythropoietic tissues. The skin reaction has clearly demonstrated that keloid neoformations respond to particular local conditions of cutaneous allergy. In conclusion the author states that the origin of the keloid scar formation was attributable in his cases to a predisposing tuberculous condition with the necessary presence of a marked demonstrable cutaneous allergy.

Action of Colloidal Silver in Peritoneal Cavity During Laparotomy—Galli made a study of the effects of electrolyzed colloidal silver (electrocollargol) when introduced into the peritoneal cavity of 105 patients on whom laparotomies were performed. By means of a syringe the author introduced the contents of from 2 to 5 ampules of electrolyzed colloidal silver, each containing 5 cc. Administration of other medications whose action might weaken or hamper the colloidal silver was abstained from. Thirty-two of the patients thus treated had acute abdominal conditions, such as acute appendicitis, circumscribed or diffuse peritonitis due to appendicitis and gastroduodenal perforations, cholecystitis, peritoneal inflammation due to disease of the adnexa, and rupture of tubal pregnancy with an infected hematocele. Aseptic laparotomies were performed on seventy-three of the patients. The post-operative course of these patients was satisfactory and no disturbances due to the introduction of the colloidal silver were observed in any case. The electrolyzed colloidal silver had no modifying effect in any case on general organic conditions, on the course of temperature, heart action and pulse and on postanesthetic vomiting. In only six cases was there any stimulation of the intestinal peristalsis observed which could be attributed to the electrolyzed colloidal silver. Of the six, three were cases of chronic appendicitis and the other three were cases of peritonitis of appendicular origin. In these cases, bowel movements occurred before the administration of enemas the third day after operation. In two cases the peristalsis was reestablished by the first day in a form of several diarrheal attacks with abundant passage of gas, temporary pains and some rectal tenesmus. In the others, one or two regular evacuations occurred without disturbances before the third day. The peristaltic action was never violent or accompanied or preceded by severe abdominal pains or by gastric cramps with severe vomiting. Six cases are insufficient to establish that spontaneous activity of the enteric tract is attributable to colloidal silver introduced into the peritoneal cavity. Colloidal silver has been shown to possess a definite value in the field of abdominal surgery. On the basis of his clinical observations the author states that colloidal silver introduced into the

abdomen, the seat of acute peritoneal processes, does not have any effect on the intestinal peristalsis which others have attributed to it. He admits the prophylactic and curative properties of colloidal silver due to a stimulation of the defensive powers of the peritoneal serous membrane.

Hypophysis and Castration Obesity—Schultze calls attention to the fact that Anselmino and Hoffmann extracted from the anterior lobe of the hypophysis a substance that produces ketonemia and is identical with one that appears in the blood after meals with a high fat content. Anselmino and Hoffmann ascribe to it a regulatory function in the fat metabolism and designate it as the anterior hypophyseal hormone of the fat metabolism. The author duplicated the studies of those two investigators. He found that under the influence of the anterior lobe of the hypophysis the ketone bodies in the blood increase, and that a substance which appears in the blood during the digestion of fat has the same effect on the ketone body content of the blood. He expresses the opinion that the anterior lobe of the hypophysis is involved in the pathogenesis of the so called castration obesity. He made fat tolerance tests on normally menstruating women and on patients with castration obesity. He did not find essential differences in the ketone body content of the blood in these two types of women, and thus these tests did not prove a direct connection between the elimination of the hypophyseal substance, producing an increase in the ketone bodies, and castration obesity. In spite of the negativity of these tests, it is possible that the anterior hypophysis plays a part in castration obesity. However, it is probable that the mechanism of the interrelation is more involved than is known at present.

Creatine-Creatinine Metabolism in Gestation—Kessler and Albers determined the amount of preformed creatinine and of creatine (expressed in creatinine) in the serum of normal, nonpregnant women and also reexamined their elimination in the urine. The amount of the preformed creatinine is constant and the creatinine value fluctuates only within narrow limits (45 mg per hundred cubic centimeters). In healthy pregnant women the creatine curve shows greater fluctuations. In the elimination of creatine the pregnant women more often show a positive value. The serum creatine and the urine creatinine show a slight decrease during pregnancy. In the last months of pregnancy the serum creatine shows strong individual fluctuations. At the onset of delivery the serum creatine value increases again and reaches its maximum at the time of expulsion. The urine creatinine curve reaches its maximum somewhat later, and during the early puerperium it decreases just like the normal creatine curve. The early puerperium is characterized by considerable fluctuations in the different values. After the third week of the puerperium the blood creatine content sinks below that of the nonpregnant women. This decrease during the later puerperium is still greater in the creatinine values of the urine. During early and late toxemia, as could be shown in some cases of hyperemesis, an increase in the total creatinine values could be observed but a decrease

in the creatine values partly compensates for the increase in the serum creatinine, that is, an increase in the serum creatinine is frequently accompanied by a decrease in the serum creatine. There is not in every case a parallelism between the height of the blood curve and the elimination values and the severity of the toxæmia.

Edema of Endometrium—Derichsweiler states that the curettage material of fifty women (aged 40 or over), who asked advice because of irregularities in menstruation, indicated the presence of edema without simultaneous hyperplasia of the glands. The edema was nearly always accompanied by hyperemia and often by hemorrhages into the mucous membrane. The author thinks that disturbances in the hormonal equilibrium at the beginning of the menopausal period are the cause of these disorders. In the increased filling of the vessels of the mucous membrane he sees the main cause of the edema of the endometrium. The greater blood supply, caused either by increased inflow or by inhibition of the outflow in turn causes an increased transudation and a decreased retrotransudation. Thus the edema of the endometrium is the result of a disturbance in the hydrostatic equilibrium between the vascular system and the tissue pressure.

Multiplicity of Duodenal Ulcerations—Just opened the lumen of the duodenum and carefully inspected the duodenal mucosa in a consecutive series of sixty patients operated on for duodenal ulcer. He found that incidence of multiple ulcerations and corresponding multiplicity of pathologic states is greater than was formerly believed. Twin ulcers ("kissing ulcers" of Moynihan) were observed in forty-six, or 76 per cent, of the cases. Scars in the vicinity of ulcers were found in eight cases. These were radiating or starlike. In the rest of the cases the author found large ulcerations involving both the anterior and the posterior wall. These he believes, were the result of coalition of an anterior wall and a posterior wall ulceration. Consideration of this group of cases suggests that multiplicity of lesions is present in 100 per cent of all cases of duodenal ulceration. These observations lend support to von Haberer's opinion that recurrent ulcers after gastric resection are overlooked ulcers. While observations on so small a group of cases do not rule out the existence of a single duodenal ulcer, they emphasize the great frequency of multiple lesions and the necessity for awareness of this fact on the part of the surgeon.

Delayed Healing of Fractures—Bankoff states that delayed healing of fractures has become more frequent and that it was observed with particular frequency in fractures the fragments of which were well placed and maintained by means of modern mechanical methods. Various biologic states were cited as the cause, stress being laid on vitamin sufficiency as well as on the disturbance in the correlation of the glands of internal secretion. No investigations of the effect of sexual hormones on the healing of fractures were made so far. Previously the author demonstrated the remarkable influence of sexual hormones on the blood picture. Enormous fall in the number of thrombocytes took place in castrated animals, while hyperhormonization in another series of animals resulted in a rise of thrombocytes to three times the original number. In the present experiment the author used healthy young guinea-pigs weighing from 250 to 300 Gm. One group was kept as a control, in another group the sexual organs were removed

and were transplanted into the third group of animals. The tibia was fractured in all the animals. The following results were observed. Satisfactory healing and a thick callus were present at the end of twenty-five days in the control group. Roentgenograms demonstrated that the fracture was not healed in the animals of the second group at the end of three weeks. The callus here was irregular and not compact. The animals of the third group on roentgenologic examination exhibited complete healing of the fracture and a thick callus at the end of two weeks. The author believes that the influence of sexual hormones is to be ascribed to its effect on the blood picture as well as to a direct effect of stimulation of the metabolism. In his treatment of patients with pseudarthrosis, the author combined the mechanical method of multiple percutaneous boring of the fractured ends with injection of an organic preparation of sexual hormones on the tenth day after the operation. The results were exceptionally favorable. Pseudarthroses of months' standing healed in a few weeks.

Studies of Cortical and Subcortical Areas—Sattler observed the cortical and subcortical areas in men in the course of brain operations carried out under local anesthesia. He found that stimulation of the cortex with a faradic current resulted in an initial hyperemia, which was succeeded by anemia. Repeated stimulation produced anemia without the initial hyperemia. The author demonstrated that the late traumatic epilepsy was caused by the loss of function of the center that regulated inhibitory stimuli, in which case a more deeply located center, whose function it is to release inhibitions became activated. When the diseased inhibitory center is extirpated, its function is taken over by an adjacent normal center with a resulting recovery. The author found that cooling of the cortex with carbon dioxide snow effected the subcortical ganglions as well, resulting in abolition of tonic and clonic states the extremities becoming flaccid. The author made the observation that in cases of epilepsy a cooled muscle group (through application of carbon dioxide snow to the corresponding point in the cortex) did not participate in tonic convulsions but went through irregular swinging movements. Isolated electrical stimulation of the subcortical layers produced tonic contractions only. It was found possible to increase the complementary activity of the adjacent tissue described by Monakow by the extirpation of the injured or diseased cortical or subcortical tissue. He found that ligation of the venous plexus lying just below the gyrus centralis posterior resulted rather promptly two hours or, at the latest, twenty-four hours later, in disappearance of the vasomotor and sensory disturbances in the spastic extremities with a return of the color and warmth similar to that of the opposite healthy extremity. In contradistinction to Forster's method of sectioning posterior roots, the author believes that his method of operating on the brain is more efficient in cases of spastic contractures with severe sensory and vasomotor disturbances.

Value of Coagulation Band in Tuberculosis—Makitra and Tyndel made Weltmann's coagulation test on 200 patients with tuberculosis. They think that in incipient cases of exudative tuberculosis Weltmann's coagulation band gives more reliable diagnostic results than does the sedimentation speed of the erythrocytes. In chronic tuberculosis, Weltmann's test has prognostic value.

Weltmann's Reaction in Estimation of Pulmonary Tuberculosis—Dissmann performed Weltmann's test 605 times on 274 patients with tuberculosis, on 9 patients with nonspecific pulmonary disorders and on 24 normal persons. He observed a shortening of the coagulation band or a deviation to the left in nearly all cases of exudative inflammatory disturbances, and the extent of the shortening usually corresponded to the severity of the inflammation. Fibrocavous tuberculosis during the interval and fibrocavernous tuberculosis frequently showed a normal coagulation band. A widening of the coagulation band was noted almost exclusively in purely productive tuberculosis and in the originally open but at the time of examination already closed and healing tuberculosis. The sedimentation reaction and the coagulation band did not always run parallel. The coagulation band seems to be more valuable for the estimation of the inflammatory process than is the sedimentation reaction.

Sedimentation Reaction in Pulmonary Tuberculosis—Muller believes that the prognosis is generally favorable when in serial examinations the values decrease slowly. High and increasing values give an unfavorable prognosis. Rest, pneumothorax treatment and specific and nonspecific therapy usually lead, together with the clinical improvement, to a reduction of the sedimentation values toward the normal. An increase in the sedimentation speed indicates complications or exacerbation of the tuberculous process, and it makes interruption of the treatment or a reduced dosage advisable. In collapse therapy (pneumothorax and phrenic exeresis), an acceleration of the sedimentation may set in at first. It is the result of the increased resorption of disintegration products, and as the improvement progresses, it disappears again. In vaccine therapy there is a slightly increased sedimentation after every vaccination, but it disappears again together with the local irritation. Noticeable fluctuations of the sedimentation speed are caused by menstruation, and for this reason the test should be made only during the intermenstrual period. To avoid prognostic errors, one should not overlook that the sedimentation reaction is influenced by the pleuritis and enteritis, which so frequently accompany tuberculosis. The author concludes that the sedimentation reaction is an important aid in the diagnosis and prognosis of tuberculosis, but he also warns against over-evaluation.

Treatment of Large Apical Cavities—Michelson stresses the advantages of apicolysis. He recommends it not only as a complementary measure to an incomplete pneumothorax but also as a preliminary operation of thoracoplasty. He points out that after thoracoplasty patients often die as the result of a caseous aspiration pneumonia of the other side, owing to the fact that, following the resection of the bones of the thorax, the patient's cough is not strong enough to expel the profuse and generally tough sputum. Frequently the sputum reaches only the trachea from which it flows into the other lung. The author thinks that this danger can be eliminated by reducing the cavity and with it the amount of sputum by an extrapleural apicolysis. The real thoracoplasty may be done later, but it may be postponed until the patient's general condition and heart have gained sufficient strength. Moreover, since apicolysis does not tax the resistance and the energy of the patients too highly, they more readily give their consent to the later thoracoplasty than is the case in a two time thoracoplasty.

Obscure Abdominal Disturbances and Their Significance—Voegel followed Libman's suggestion and tested the individual sensitivity to pain by exerting pressure on the mastoid process and then proceeding to press in the direction of the styloid process. He concludes that abdominal disturbances

have a normal symptomatology only in sensitive patients, while in hyposensitive persons there are only rudimentary symptoms or none at all. Thus it is of the greatest significance for the estimation of the subjective symptoms whether a patient belongs to the sensitive or the hyposensitive group. This knowledge is also helpful in differentiating patients with organic disorders from those in whom the symptoms are of nervous origin.

*Is Short Wave Therapy of Gastric Ulcer Advisable? Mahlo—p. 403

Sulphur Therapy in Psychoses—Langeluddeke commenced sulphur treatment of schizophrenia in 1927. At first he used a 1 per cent only suspension of sulphur for the intramuscular injections but, because of pain, he abandoned it and now is using a 0.5 per cent sulphur preparation, which in addition to the sulphur also contains an anesthetic. He begins the injections with 2 cc and repeats the treatment every second day. At the second and third injections the same dose often produced a higher temperature, but in cases in which the temperature had a tendency to decrease with successive injections the dose was increased by 1 or 2 cc. The treatment was considered completed only after at least six injections had been given. The general reactions are comparatively mild and the dangers are much less than in malaria therapy. In order to be able to determine the value of this sulphur therapy, the author compared the thirty-five schizophrenic patients he treated with sulphur with sixty who had not been treated. He found that among the treated ones the number of those who showed improvement was more than 20 per cent higher than among those who had not been treated.

Short Wave Therapy of Gastric Ulcer—Mahlo employed short wave therapy in the treatment of chronic gastric ulcer. In twenty-five persons who were treated with short waves under identical conditions, a considerable increase in the gastric motility was noted. Observations before the roentgen screen revealed a considerably increased peristalsis during the short wave treatment, but with the cessation of the irradiation there was a gradual decrease in the peristalsis. The secretion of the gastric juice likewise was increased under the influence of the short waves, but the effects on the acidity were quite different, for it was reduced in nearly all cases. The author concludes that in the majority of cases of chronic ulcer the short wave therapy produces effects that promote cure. He cites one case in which prolonged treatment with the short waves led to gastric hemorrhage, and for this reason he advises caution. The treatment should begin gradually. Most patients find the treatment pleasant and state that it alleviates the pain.

*Complement Titer of Human Serum and Its Changes Following Rheumatic Infections. B. Buchholz—p. 330

Glycogen Storage Disease—Biedermann and Hertz observed in a child with glycogen storage disease and dwarfism that the hypoglycemia is hardly at all influenced by epinephrine and that this slight reaction to epinephrine is dependent on the time elapsed since eating and on the time of day. They consider the possibility of a connection with the insulin secretion. The acetonuria during the fasting period is increased by epinephrine. Patients with glycogen storage disease are highly susceptible to insulin.

Complement Titer of Human Serum—Buchholz shows that the complement titer represents normally a rather constant value. The ordinary infectious diseases cause hardly any changes, but acute rheumatic infections, which include acute polyarthritis, endocarditis, diffuse glomerular nephritis, chondritis, pleurisy and some other organic diseases, produce a reduction in the complement titer that may lead to a complete abolition of this function of the serum. The duration of the reduction differs. An especially severe antigen-antibody reaction in an organism that has been sensitized by an infectious focus is considered the cause of the reduction in the complement titer. On this basis, the rheumatic infection presupposes the presence of an infectious focus that causes the sensitization. Horses, which for the production of a potent antitoxic serum are injected with increasing doses of a pathogenic organism, finally develop arthritis and endocarditic processes of the rheumatic type. This observation supports those investigators who tried to show that as the result of focal infections the organism becomes allergic, so that it reacts to new infections with organic reactions that resemble the changes in rheumatic infections. The focal infections sensitize the organism and lead to immunization. At the time when larger quantities of antigen enter the organism, the increase in antibodies prevents the development of a true sepsis. An extraordinarily active antigen-antibody reaction sets in and the complement is reduced. This reduction is generally of a temporary nature for the antigen is destroyed and the complement is quickly replaced. There is a second possibility. The complement function may suffer so under the shock of infection that it is not equal to the requirements. There may be a prolonged deficiency in the complement and as a result the disease process does not definitely terminate. Moreover in the absence of the protective function of the organism, other infectious foci may become active. Thus it is not surprising that in the blood of patients with rheumatism there appear pathogenic organisms such as tubercle bacilli (Lowenstein) which have no etiologic connection with the disorder.

 Pulmonary Tumors E. Hamitz—p. 382

Neuroregulation of Thyroid—Sunder-Plassmann studied the innervation of the thyroid. In spite of the great number of sympathetic nerves it is highly probable that the thyroid does not have a single peripheral ganglion cell. The latter factor makes peripheral automatism by nervous autoregulation impossible, and, since every normal thyroid cell is under the influence of an intraplasmatic, sympathetic terminal reticulum, the normal activity of the thyroid is entirely dependent on the central nervous system (including the sinus caroticus) from which it receives regulatory impulses by way of the sympathetic nerves. If these central nervous impulses become abnormally strong as the result of psychic trauma, of continuous psychic alterations or of chemical or hormone changes (iodine intake or hypophyseal disturbances), a hyperfunction or a dysfunction of every thyroidal cell develops. Up to this stage at which the condition is still reversible, the term *hyperthyroidism* (to be differentiated from *exophthalmic goiter*) can be employed. However if the harmony is not reestablished the disorder progresses. It appears as if the pathologic secretion that develops as the result of the dysfunction of the thyroid cell has an injurious effect on the terminal sympathetic reticulum and that it may cause its complete degeneration. By this the

thyroid cells are cut off from the nervous system, so that they do not receive regulatory impulses, and thus the irreversible *exophthalmic goiter* develops. In addition to destroying the terminal sympathetic reticulum, the abnormal secretion of the thyroid irritates the entire sympathetic nervous system and causes disastrous increases in the tonus. The circulatory regulation becomes impaired and this in turn leads to an involvement of the heart and the blood supply of the brain, because on account of the impaired nervous apparatus of the thyroid the regulatory nervous impulses from the carotid sinus have either no effect or only an abnormal one on the vasculatory system of the thyroid and a normal regulation of the cephalic blood stream became impossible.

Insulin and Permeability of Kidneys to Sugar—Bufano reports eleven series of experiments on dogs and draws the following conclusions. 1. In hyperglycemia, the increased permeability of the kidneys to dextrose depends largely on the autonomous increase of the activity of the kidneys and partly on the stimulation of the vagus, which is produced by the hyperglycemia and most probably to a certain extent also on the hypersecretion of insulin which can be observed in experimental hyperglycemia. 2. Insulin does not reduce the permeability of the kidneys to dextrose, for in none of the author's experiments was even the slightest reduction in the permeability noticeable after treatment with insulin. 3. In renal diabetes and in experimental phlorizin diabetes, insulin increases the permeability of the kidneys to dextrose. 4. The author's experiments do not furnish definite proof that insulin increases the dextrose permeability of normal kidneys. If it is taken into consideration that insulin reestablishes the insulin increase in the sugar permeability of the kidneys of atropinized dogs and also that insulin, which is injected directly into the renal artery occasionally increases the sugar permeability and then again does not, the conclusion is justified that insulin increases the permeability inconstantly and moderately and that consequently it decreases the sugar threshold of the healthy kidney only slightly.

 Disease of Civilization E. Benjamin—p. 368

Protein Consumption and Requirements—Heupke shows that the protein minimum of most diets lies between 30 and 40 Gm a day. Millions of human beings fill their protein requirements with an intake of from 50 to 70 Gm without suffering an impairment of their health, 80 Gm of protein a day must be considered entirely adequate. Impairments traceable to a deficient protein intake are unknown today. More over in a freely chosen diet the protein never goes below the minimum requirements. The author thinks that the fixing of

an optimal amount of protein can be abandoned the more so since the knowledge about this problem is not yet sufficiently exact to decide on a definite quantity. He thinks that the consumption of unusually large amounts of protein is not advisable. He calls attention to the fact that monks who live on a purely vegetarian diet rarely have hypertension while monks who take a mixed diet have hypertension about as frequently as do other population groups.

Conservative Treatment of Varicose Veins—Nobl discusses mainly the obliteration treatment by means of injection of hypertonic dextrose or salt solutions. He points out that in the varicose syndrome embolism is not as dangerous as it is in surgery, and he emphasizes that in the obliteration treatment of varicose veins the danger of embolism is much less than in other forms of treatment. Another advantage of the obliteration treatment is that it can be done irrespective of the presence of ulcerations and of severe cutaneous changes, while such conditions contraindicate surgical treatment. Obliteration treatment may be resorted to even during the first half of pregnancy, but it should be avoided during the second half not only because of the extreme dilatation of the vessels but also because of hormonal changes in the coagulability of the blood. Obliteration treatment is contraindicated in case of profuse congenital, neviform venous convolutions after recent spontaneous thrombophlebitides and after severe disturbances in the circulatory apparatus. The treatment should not be begun until the patency of the deeper veins has been established.

Operations for Cholecystitis Without Stones—Schmechel states that the prognosis of a cholecystectomy as far as permanent cure is concerned is worse in proportion to the amount of pathologic alteration present at the time of the operation. The less pathologic alteration in the gallbladder the poorer the result. He reports a follow-up study of sixty patients on whom cholecystectomy was performed in the absence of stones. Only fourteen patients (23.4 per cent) were completely relieved of the symptoms for which they were operated on. Fourteen were improved only after one or two years of Karlsbad treatment, and five of the remaining thirty-two were not improved in any sense. Their subsequent cure resulted only after other therapeutic measures, in one case after appendectomy, in two after passage of renal stones, in one after operation for peptic ulcer, and in one after treatment of adenitis. Two patients were rendered symptom free after treatment of a disclosed latent syphilis. General nervous and functional symptoms were found in eight patients who came to examination. In fifteen patients who continued to have the same symptoms as before the operation namely periodic attacks of colics and pain in the back and in the shoulder region there were found years after the operation typical Head zones involving the area from the tenth to the twelfth thoracic nerve. These patients were again treated medically from time to time. The

figures presented correspond with those of Stanton, who in a study of 113 patients found 53 per cent improved and 43 unimproved as well as with those of Gosset, who reported ten cures in a group of thirty-two. The author quotes his chief, von Haberer, as being opposed to the removal of the gallbladder in the absence of stones even if signs of stasis are present. If operated on at all the stasis should be relieved not by a cholecystectomy but by a cholecystoduodenostomy. This operation was performed in von Haberer's clinic with good results in exceptional cases of stasis of the gallbladder.

Treatment of Menstrual Abnormalities by Means of Parathyroid Extracts and Calcium G Bakacs—p 568
Table for Examination and Operation with Arm Support for New Apparatus for Intravenous Injection G von Bud—p 572

Treatment of Dermatoses of Pregnancy—Lysander resorted to autohemotherapy in the treatment of thirty-one pregnant women with various cutaneous disorders. Erythema urticaria and pruritus were predominating (twenty-nine cases) but two women had eczema. The pruritus was particularly annoying. In the majority of women the dermal disturbances developed during the last two months of pregnancy and only in a few cases already during the fifth or sixth months. The technic of the autohemotherapy is the following. The blood is withdrawn from the cubital vein is kept in the syringe for several minutes until coagulation has set in and is injected into the gluteal muscle. At first the author employed comparatively large doses (from 15 to 20 cc), but later he used small gradually increasing doses, usually beginning with 1 cc. Experience so far seems to indicate that the small doses give the same favorable results. The intervals between the injections should be two or three days. The results of autohemotherapy were highly satisfactory. In the majority of cases a single injection was sufficient, but some required two and others three, four or five. In six cases the pruritus was localized on the vulva and in three of these there was sugar in the urine. Formerly such cases were treated with a diet deficient in carbohydrates and occasionally this was effective. The author combined the dietary measures with the autohemotherapy and gained the impression that this combined treatment is superior to the dietary measures. He emphasizes that autohemotherapy is simple, inexpensive and effective and that it involves no danger.

Parathyroid Extract and Calcium in Treatment of Menstrual Abnormalities—At first Bakacs resorted to the application of parathyroid extract and calcium during the menstrual period of women with abnormalities of this function, but later he tried the prophylactic application and found it more effective. Beginning from four to six days before the expected menstruation the women are given daily intragluteal injections of a preparation containing 50 Collip units of parathyroid extract and a quantity of calcium gluconate corresponding to 0.1 Gm of calcium. The result of this prophylactic treatment was that 70 per cent of the cases were favorably influenced. The author thinks that the curative effects produced with this medicament are due not merely to the action of calcium but also to the direct or indirect action of the hormone on the hemostatic mechanism.

Operation in Acute Appendicitis—Kogon presents an analysis of 150 cases of acute appendicitis in which operation was performed without delay and without regard to the stage of the disease. The results convinced him that systematic operating in every stage of acute appendicitis is more rational.

than watchful expectancy after the forty-eight hour period adopted by many surgeons. Watchful expectancy is only relatively safe in mild catarrhal cases after the twenty-four or forty-eight hour period. In the more destructive form of the disease, this policy, owing to the progression of pathologic alterations, is decidedly hazardous. In view of the impossibility of establishing an exact pathologic diagnosis before the operation, the method of waiting appears to be both purposeless and dangerous. The presence of an induration or of resistance in the right lower abdominal quadrant is an important sign of a grave destructive process and therefore constitutes a clear indication for operative intervention. The subsidence of the acute symptoms in the first three days, as well as in a later period, is no guaranty of safety and must not be regarded as a contraindication to the operation. An interim operation is not always a safe operation. The existence of an induration, even if diminished in the process of waiting, constitutes a constant danger of flare up of a dormant latent infection in the tissues. Furthermore, operation in the late cases frequently develops into an extensive and damaging procedure because of the firmness of the adhesions, endangering the life of the patient. The removal of a purulent, gangrenous or perforated appendix results in the disappearance in a few hours of the pain and the other symptoms of peritoneal inflammation, regardless of the time of intervention. The evaluation of the question of the time of intervention must be based not alone on the mortality statistics but on the evaluation of the character of the entire material as well.

Urobilin Excretion and Blood Destruction Index.—Lichtenstein studied the urobilin excretion of a number of Europeans on a normal mixed food diet, ten European vegetarians and fifteen Javanese natives. He found that the average excretion of urobilin from the fecal matter of an average European weighing 154 pounds (70 Kg.), amounts to from 135 to 150 mg daily, whereas that of an average Javanese, weighing approximately 121 pounds (55 Kg.) comes to only 75 or 80 mg. The author attributes this lower rate of excretion in the Javanese to a consumption of foods poor in animal protein. The average daily excretion of urobilin in ten healthy vegetarians in Amsterdam was estimated to be about 75.4 mg. Persons suffering from constipation evinced a marked diminution in the excretion of urobilin. As a consequence of these investigations the author discards the assumption that by estimating the urobilin excretion one should be able to calculate the average time of survival of the erythrocytes in an absolute number of days. He found the blood destruction index, as proposed by Lichtenstein and Terwen, still of great value.

- Acute Appendicitis in Young Children. E. Pettersen—p. 296

Operative Treatment of Elephantiasis.—Moene reports two cases of massive elephantiasis in which wedge-shaped excision done with the electric knife and removal of the underlying fascia according to Kondoleon gave good results. The first patient was a woman, aged 66, with elephantiasis of the left leg which had developed slowly during the course of thirty-nine years, and the leg became practically normal. The

second patient was a woman, aged 47, with elephantiasis of the left lower extremity of twenty-eight years' duration. The excision was done in three stages, and Handley's operation was performed on the thigh. Considerable reduction in size resulted.

Internal Anesthesia in Cauterization of Pleural Adhesions.—Haave says that as cauterization of pleural adhesions has become more frequent and more complicated anesthesia has more often become necessary. To overcome the difficulties in this connection he has devised a stiff cannula of the form and size of the cautery and ending in a point 3 cm long and at the handle end in a 5 cc syringe. If anesthetization is called for, the cautery is readily replaced by this cannula, the same field of vision is kept, and certain anesthesia is attained.

Elimination of Leptra Bacilli in Lepers.—Stein and Steperin succeeded in finding lepra bacilli in the nasal mucus in eleven patients without macroscopic changes in the mucous membrane. They also obtained positive results in 'healthy,' apparently normal portions of the skin on examination of lymph from the tissue and of contents of blisters produced by freezing, the latter is the preferred method. By it lepra bacilli were demonstrated in three patients who no longer showed symptoms of leprosy and in whom, even after use of potassium iodide, bacilli could not be found in the nasal mucus.

Roentgenokymography of the Heart.—Frimann Dahl asserts that the plane kymogram is of great help to the roentgenologist in the determination of the form of the heart and the strength, frequency and rhythm of the different pulsations. The method is perhaps of the greatest value in topographic examinations, especially in cases of tumors and tumor-like changes near the heart. Here the plane kymogram is far superior to the ordinary teleroentgenogram.

Ugeskrift for Læger, Copenhagen

- Treatment of Pariarticular Disorders with Petrolatum Packs. E. Nyrop—p. 248

Agranulocytosis.—In the case described, in a woman aged 42, with obesity, chronic polyarthritis climacteric disturbances and slight hypothyreosis, one tablet of lealgin (0.22 Gm of amidopyrine plus 0.03 Gm of diallylbarbituric acid) was given from one to three times daily for five months in 1930-1931, without apparent injury. In 1932 one tablet was given three times daily for one and one half months before definite symptoms of agranulocytosis were seen. Although the dosage was increased to one tablet four times daily, recovery from this attack of agranulocytosis occurred. The first recurrence appeared six weeks later and a repeated recurrence in two months. After administration of twenty five barbituric tablets, begun one month later, when the blood picture was about normal, and distributed over six weeks the granulocyte count fell to 8 per cent, and after a subsequent twenty five tablets, distributed over sixteen days, the granulocyte count was 7 per cent, a value possibly increased because of administration of pentnucleotide. Amidopyrine was discontinued. The granulocyte count rose to 25 per cent. Andersen says that the case agrees with the five nosocomial cases reported by Holten and his associates but he is inclined to ascribe the injurious effect to the pyrazol ring rather than to the benzene ring. The patient's improvement under the present thyroid therapy is seen as an indication for continuation in the hope of influencing endogenous factors, which may perhaps bear a relation to her agranulocytosis.

Amidopyrine in Agranulocytosis.—Seemann found that amidopyrine or its combinations had been used in thirteen of thirty-six cases of agranulocytosis from 1928 to 1933 and had not been given in fifteen cases, in the remaining eight cases the information was incomplete. In most of the thirteen cases the dosage of amidopyrine to some extent supports the possibility that this medicament played a part in the origin of the agranulocytosis.

POTENCY OF MILKS FORTIFIED WITH RESPECT TO ANTIRACHITIC PROPERTIES

CLINICAL TESTS AND A PROPOSED METHOD
OF PROCEDURE

MARTHA M ELIOT M D
AND
GROVER I POWERS M D
NEW HAVEN, CONN

During the past few years there has been developing increasing pressure from various sources to "fortify" natural foods in one way or another, but notably with certain vitamins and mineral salts. There are many aspects of this subject which require the most careful consideration of physicians, nutritionists, health officers and manufacturers of food products, but it is certainly true that, before commercial interests enter largely into this field, many more carefully controlled clinical studies should be made than are now available. It needs to be widely recognized that while the fundamental facts in respect to the role of the vitamins and mineral salts in nutrition have been established largely by the use of experimental animals, the accurate application of these facts to man must be determined by clinical studies.¹ Furthermore, it is imperative that an adequate and uniform procedure in investigation be adopted in each field of study by those who may attempt to evaluate clinically the role of "fortified" food substances in human nutrition.

The present paper has to do with a proposed standard procedure for the appraisal by clinical tests of milks "fortified" with respect to their antirachitic properties. Largely because of the widespread need throughout a large section of the United States for some measure to prevent rickets and its associated disorders and because of the numerous antirachitic agents and the various methods of giving to foods antirachitic properties, the activity of nutritionists and representatives of food companies and dairies has been especially great in this vitamin D field of food "fortification."

Since rickets is principally a disorder of infancy and since the natural food of infants is milk, the chief concern of the various interested groups is in conferring antirachitic properties on this food. Milk may be used dry, evaporated or in its usual form and may be put on the market in each of these states after having been "fortified" with antirachitic properties. This may be accomplished either by irradiation with ultraviolet

energy, by the addition of vitamin D concentrate from cod liver oil or of viosterol (irradiated ergosterol) and by feeding irradiated yeast to cows. Obviously, in this matter many problems—medical, public health and commercial—present themselves, notably, these are the existence and degree of antirachitic potency conferred on the milk, the method of expressing potency in international, Steenbock or other units, the relative biologic merit of the various processes, the effect on other properties of the milk the practicability and cost of commercial production, and the possibility and feasibility of routine assay and public health control. However, to establish the existence and degree of antirachitic potency for infants of any given "fortified" milk is surely the first and sine qua non requirement in this ever enlarging domain.

Clinical studies may be designed to test the antirachitic value of a given "fortified" milk either by the prevention or by the cure of rickets. Both methods must be used if the antirachitic properties of the milk are to be understood. The preventive type of study has certain advantages and a method of procedure for such is here outlined. Today it is easier to obtain in any one locus a group of normal infants in the period of most active growth—the first few months of life—for a preventive test than to obtain a group of infants each of whom has active rickets of approximately the same degree of severity for a curative test. Roentgenograms must be taken in both "curative" and "preventive" methods of testing potency. In a "curative" test, calcium and phosphorus determinations on the blood serum are also required, since vitamin D curative effect is thereby most delicately and promptly demonstrated. On wide-scale investigations that must be conducted over a considerable period of time, such chemical determinations offer obvious practical difficulties. In "curative" tests, fewer children per group might be required than in "preventive" tests, but to insure a carefully controlled investigation it might be desirable to institutionalize the children in a "curative" study. Such a procedure is not only very costly but may be difficult to carry out. Lastly, the "preventive" test is in line with the fundamental ideal back of the use of a "fortified" vitamin D milk, namely, the routine prevention of rickets in a simple, natural manner which requires no special attention or disturbance on the part of either mother or infant.

PROPOSED METHOD OF PROCEDURE

The proposed method of procedure for making clinical tests of the preventive potency of milks "fortified" with antirachitic properties is as follows:

The studies must be carried out, of course, on artificially fed infants. Groups both of normal and of premature infants must be studied.

From the Department of Pediatrics Yale University School of Medicine.
1 Hess A F and Lewis J M. An Appraisal of Antirachitics in Terms of Rat and Clinical Units. J A M A 101 181 184 (July 15) 1931.

At least one half of the normal children should belong to the races especially susceptible to rickets, e g, Italians and Negroes

At the time the infants are enrolled in the study group they should be, preferably, under 6 weeks of age—certainly not over 8 weeks—since the first months of life constitute the period of most active growth and the one when rickets most readily develops. The prevention of rickets in children of this age period, next to prevention of the disease in premature infants, is the most rigorous clinical requirement for testing a vitamin D fortified milk, it is by such a test, however, that a milk to be used for the routine prevention of rickets must be judged

The children should be under observation until they are at least 6 months of age, in some cases longer

The infants must live in the north temperate zone and the study should be conducted preferably from October to May, infants should not be enrolled who were born prior to the middle of September. This requirement is necessary in order that ultraviolet radiation from sunlight may not enter into the investigation as an important additional antirachitic factor. The mothers of children in the study group should not be instructed to give their infants sun baths, but they cannot reasonably be expected to keep their children continuously indoors. The investigations should be conducted in the winter, since then the factor of sunlight as a contributory antirachitic measure is thus reduced to minimal importance.

No infant should be enrolled who has had previous antirachitic treatment

No other antirachitic should be given during the investigation than the "fortified" milk under study and the possible unprescribed outdoor ultraviolet irradiation of winter months

At least fifty infants should be studied in each experimental group, more than this number should be enrolled at the beginning, because a certain number, for one reason or another, will not be followed throughout the duration of the study period

It is desirable that the infants studied be chosen from well-baby clinics. Infants in institutions such as hospitals or orphanages bring in too often the large factor of infections or slow growth

The infants must be carefully examined and roentgenograms of wrists and forearms must be taken at intervals of four weeks according to a uniform standardized technic.² The primary basis for appraisal in these tests should be changes in the roentgenographic picture, clinical observations are only contributory and supplementary. It is essential that the roentgenograms be interpreted by some person with special experience in this field

There must be accurate measurements at each examination of the growth of each child in respect to length and weight

There must be adequate follow-up visits of each infant in its home by a specially instructed nurse. Records must be made of pertinent incidents in the life of each subject, notably the occurrence of infection and other illness. Special attention must be directed toward the care used in preparing the milk mixture given the infant. Accurate record of the amounts of milk taken must be made, for only in this way can the amount of

antirachitic substance ingested be determined. It is obvious that this matter of careful follow-up visits by a well trained nurse is of the greatest importance, since failure to prevent rickets might be due to the use of some "unfortified" milk or other food rather than to lack of potency of the antirachitic milk which the child was supposedly taking. In order to minimize errors of this type an adequate amount of the "fortified" milk should be supplied for the entire household of the infant under investigation and strong effort made to have this milk the only kind used by the family

There must be as great a degree of uniformity in the type of feeding which is prescribed for the infants being studied as is compatible with their well being. The milk mixtures should, if possible, contain the same added carbohydrate in approximately the same relative amounts, likewise the mixtures should contain approximately the same relative amounts of fat. All infants should receive the same antiscorbutic substance, and extraneous vitamin D containing foods, such as egg yolk, must be excluded

Careful record of all data must be kept

Each study should be carried out under the direction of an experienced pediatrician with such other assistants as may be required. This director must be able not only to correlate and appraise data but also to inspire assistants and mothers with enthusiastic and intelligent interest. Only in this way can a degree of accuracy be achieved which, while not comparable to that of many laboratory biologic tests, is nevertheless acceptable from a clinical standpoint in the light of our present knowledge

PREVENTION OF RICKETS BY MILK FORTIFIED WITH VITAMIN D FROM COD LIVER OIL

(150 STEENBOCK UNITS OF VITAMIN D PER QUART)

WILLIAM R WILSON, MD
NEW HAVEN, CONN

The present study was undertaken for the purpose of testing the antirachitic value for infants of vitamin D concentrate from cod liver oil when it was incorporated in milk at the dairy. Though the concentrate was known to be effective in the treatment of rickets in rats,¹ its efficacy in the prevention and treatment of that disorder in infants as compared with that of cod liver oil was not known. Furthermore, the investigation was considered of special value since it offered an opportunity to elaborate a method of making clinical tests of various substances that contain vitamin D, with a view to comparing their relative efficacy in the prevention of rickets in infants.²

The early studies of Barnes, Brady and James³ showed that viosterol was less effective in infants than

From the Department of Pediatrics Yale University School of Medicine and the Visiting Nurse Association of New Haven
The cost of this investigation was defrayed in part by a grant from the National Oil Products Company of Harrison N J. The milk was supplied by the Brock Hall Dairy Company of New Haven Conn.

hydrate. Cane sugar was the carbohydrate used as a rule. Six babies were given dark corn syrup instead of cane sugar. For two weeks in January through a misunderstanding 200 units of cod liver oil concentrate was added to each quart of milk used instead of the 150 units originally decided on. Table 2 shows the average amounts of milk reported to have been taken daily at different age levels by the total group studied and by subgroups divided according to the maximum degree of rickets found at roentgen examination during the period of observation. It may be seen that the infants who did not develop rickets and those that developed only slight rickets received on the average about the same amount of milk and consequently about the same number of units of vitamin D at corresponding ages. Comparison shows, however, that in general

4 Hess A F and Lewis J M Milk Irradiated by Carbon Arc
Lamp Clinical and Laboratory Study of Rickets J A M A 99 647

somewhat less milk was taken by the two infants who developed a moderate degree of rickets than by the group as a whole. This is of considerable significance, as will be pointed out later.

The milk mixtures were cooked in a double boiler twenty minutes. Orange juice or tomato juice was given from the time of the first visit and cereal added to the diet when the infants were 4 months old. The cereal used was farina and each infant received gruel made from about 20 Gm of dry cereal daily. Vegetable puree was given when the infants were 5 or 6 months old. The diet offered met all the known nutritional requirements of the infant, with the exception of vitamin D. The only appreciable source of vitamin D in the diet was the cod liver oil concentrate in the milk. There were two instances in which infants received additional amounts of antirachitic substance in the hospital by mistake (U B and E B, table 9).

Goldblatt⁵ is of the opinion that the absence of vitamin D is the only important factor in the production of rickets in the infant. Though a diet of low calcium and phosphorus content is essential for production of rickets in the rat, infants develop rickets readily on an adequate mineral intake in the absence of vitamin D. Computation showed that the diet recommended in this study contained what was believed to be an adequate amount of both calcium and phosphorus.

RESULTS OF STUDY

As has been pointed out, evidences of rickets were sought by physical examinations and through roentgenograms of the bones of the forearm repeated at monthly intervals. All of the thirty-three infants had four examinations each, twenty-three had five examinations and eight had six examinations. The infants that did not have the fifth or sixth examination were those enrolled in January or February.

Clinical Signs of Rickets—Clinical signs of rickets were found in six infants and are given in table 3. In no instance were the clinical signs marked, and all disappeared spontaneously before the end of the study.

Roentgenographic Evidence—For an investigation of the sort here described it is believed that roentgeno-

graphic evidence of the condition of the infant's bones is of much greater value than the clinical evidence obtained at physical examination, since the former is an objective record of progress that can be referred to again and again, whereas the latter is largely a subjective estimate that permits a wide range of error. The evaluation⁶ of the condition of the bones shown by roentgenogram was based on standards established

during earlier studies in New Haven.⁷ The scheme of diagnosis differentiated between bones that showed evidence of active rickets with no visible fresh lime salt deposit—the so-called A type of rickets, bones that showed evidence of active rickets with a greater or less degree of healing indicating that the process was “under control,” the so-called B type of rickets, and bones that showed advanced healing, the C type. In addition, the scheme allowed for classification of those

Chart 1—Number of infants examined at each specified age period and roentgen diagnosis made

bones which were thought to be normal, E, and those which, though probably normal, raised some question or doubt in the examiner's mind, D. The severity or degree of the rachitic process was indicated in the diagnosis as slight or first degree, moderate or second degree and so on.

Each film taken in the series was studied independently and, after a diagnosis had been arrived at, comparisons were made with the films taken previously. It was believed that the success of the antirachitic treatment should be based on the presence or absence of evidence of rickets in any one of the films in each individual series, on the severity of the process at any time and on the tendency for the process to recede without change in the daily regimen. Study of the roentgenograms for the thirty-three infants showed that the maximum degree of rickets found at any time during the period of investigation was as follows: no rickets, one, doubtful diagnosis (considered normal), thirteen, slight rickets, seventeen, moderate rickets, two.

Chart 1 shows the number of infants examined at certain specified age levels and the roentgen diagnoses at each age. The shift in the majority of diagnoses with advancing age from normal to doubtful and then to slight or moderate rickets and the ultimate receding of the disease can be seen.

The course of the rachitic process has been plotted for each of the nineteen infants who at some time during the period of observation developed roentgenographic evidence of rickets and is shown in chart 2. It will be seen that during the period of observation healing occurred in the case of the two infants who developed moderate rickets (F C and A A), demonstrating that they were in no sense “refractory” cases. Of the seventeen infants with slight rickets, ten showed advanced healing or normal bones at the last observation, four were definitely under control, and three were still too young at the last examination to determine whether the process was still active or adequately con-

trolled The case histories of the two infants who developed moderate rickets were as follows

F C was a normal, full term, rapidly growing male infant whose mother was Polish. He was first seen at 5 weeks of age and not again until 11 weeks, at which time a roentgenographic diagnosis of moderate rickets was made. During this interval he had gained 1,840 Gm on an average of 21 ounces of milk daily⁸ (111 rat units of vitamin D). From the eleventh

nosis and the average number of rat units of vitamin D received daily in the periods between roentgen examinations

All the infants had attained at least the average length and weight for their ages before the end of the study

Table 4 shows the average weekly gain in weight and growth in length during periods of about four to

* Figured for periods of approximately four to six weeks immediately preceding the second and each subsequent roentgen examination, infants arranged according to maximum degree of rickets found by roentgen examination during period of observation
† Second examination was at 11 weeks the average gain for A A covered a period of four weeks that for F C a period of six weeks
‡ Length not reported

to the fifteenth week he gained 750 Gm in weight on 23 ounces of milk daily (108 units). The rapidity of gain of this infant was, however, no greater than that of certain other infants who did not show more than a slight degree of rickets, but the quantity of milk taken daily was less. F C was an illegitimate child and soon after the third roentgen examination was removed from his home to an institution. Almost at once he developed acute otitis media. Furthermore, from the fifteenth to the nineteenth week, though he was receiving 25 ounces of milk daily (118 units) he gained only 200 Gm. From the nineteenth to the twenty-fourth week he again gained 750 Gm and was receiving 30 ounces of milk daily (141 units). As will be pointed out later, it is believed that the simultaneous decrease in rate of growth after the fifteenth week and the increase in the amount of milk taken at this time together so increased the number of units of vitamin D consumed daily per unit of growth that healing of the rachitic process was brought about.

A A, the other infant who developed a moderate degree of rickets, was of Italian parentage and, though he looked like a premature infant, was said to have weighed 2,600 Gm at birth. At the first examination at 7 weeks of age, he weighed 2,500 Gm. He gained in weight rapidly and consistently, reaching 6,300 Gm at 21 weeks of age, when the diagnosis of moderate rickets was made. As he was smaller than the average the total amount of milk taken and consequently the total amount of antirachitic vitamin was less than that taken by others in the group. Later not only was his growth somewhat slower but he also received more milk as can be seen from table 2.

Growth and Development—The progress and general development of the infants on the regimen described was apparently normal and satisfactory. Table 9 gives the data obtained at each examination, showing age, weight, length, roentgenographic diag-

nosis and the average number of rat units of vitamin D received daily in the periods between roentgen examinations. Each figure represents the average gain taking place during the four to six weeks period just preceding those examinations that fell within the specified age range. The average gains for the total group are shown and for subgroups divided according to the maximum degree of rickets found during the period of observation. It will be seen that the infants who were found to have slight rickets gained weight more rapidly on the average than did those who showed no rickets and also grew on the whole somewhat faster in length. Of the two infants who developed moderate rickets, one (A A) gained weight throughout the period of obser-

Chart 2—Roentgen diagnosis at specified age periods for nineteen infants who developed rickets during the period of observation

vation considerably faster than the average for the group as a whole and also grew faster in length. The other infant (F C) gained in weight rapidly up to the fifteenth week and then, coincident with otitis media, gained very slowly for a month. Between the nineteenth and twenty-fourth weeks the gain in weight was again more rapid. The growth in length made by this child (F C) was greater during the early weeks than that of the total group.

⁸ For two weeks during this period milk containing 200 units per quart was given by mistake.

The musculature and general appearance of all the infants was excellent at the end of the study. Of the fourteen infants who reached an age of 26 weeks or more at the last examination, nine sat alone well and five sat with support, four had two or more teeth, ten had none. The fontanels diminished in size in each case and the heads increased in circumference at the normal rate.

The incidence of infections between January and May, while apparently high, did not seem excessive for children from homes with poor hygienic conditions. On the whole the infants with infections did as well as other children in the hospital and dispensary service at the time, and recovery in every case was complete and uneventful. During the five months of the study, infections occurred among the thirty-three infants as shown in table 5.

Relation of Amount of Vitamin D Taken and of Growth to Development of Rickets—The average number of units of vitamin D taken daily during successive periods of approximately four to six weeks each has been calculated from the quantity of milk consumed and the figures are given in table 6 for the total group of infants and for the three subgroups, arranged according to roentgen diagnoses. As in table 4, the periods used for calculation are those occurring between successive roentgen examinations. There was practically no difference in the average total amount of vita-

higher than the average number of units per weekly gain taken by those who showed slight rickets. Furthermore, it is considerably higher than the number of units taken per weekly gain in weight by the two infants who developed moderate rickets, with the one exception of the amount taken by F. C. in the period preceding the examination at 19 weeks of age. The abrupt slowing in gain in weight that occurred at that time (as mentioned in the case history) accounts for the large number of units of vitamin D taken per hundred grams gain in weight and, in all probability, for the fact that healing of the rachitic process also began at this time. In each group of infants, as would be expected, the amount of vitamin D taken per unit of gain in weight increased with increase in age. This is explained not only by an increase in the amount of milk consumed but also by the fact that gain in weight had become slower.

Table 8 shows similar data except that the units of vitamin D are calculated per millimeter of weekly growth in length. A similar relationship is shown between the amount of vitamin D received per millimeter of growth in length and the maximum degree of rickets found during the period of observation, but it is somewhat less striking than that shown in table 7.

COMMENT

Bills, Honeywell, Wirick and Nussmeier⁹ have analyzed the roentgenograms of approximately 5,000 rats treated in routine assays of material that contained vitamin D. By estimating the amount of healing indicated by the line test and comparing it with a photographic standard graduated in degrees 1 to 8, they worked out a quantitative relationship between the degree of healing and the number of units of vitamin D administered. Hume, Pickersgill and Gaffikin¹⁰ compared the ash content of the bones of rats with the amount of vitamin D administered in a curative test and were also able to demonstrate a relationship between the number of units administered and the amount of healing produced. In the study of infants here reported no attempt has been made to arrive at any such numerical relationship, because of the small number of cases. The development of more than a mild degree of rickets in two infants is not, in our opinion, a wholly satisfactory result under the rigorous conditions necessary for testing a rickets preventing substance that is being considered for widespread general use. Because of the spontaneous healing that occurred in these two cases when the rate of growth became slower and the amount of milk increased, it is believed that a larger amount of the vitamin D concentrate would in all probability have kept the rachitic process from advancing to a moderate degree. How much more vitamin D in the form of vitamin D concentrate of cod liver oil would be needed to prevent the development of rickets—at least that of a moderate degree—can be determined only by further clinical tests.

SUMMARY

1. A clinical study was made of the rickets-preventing efficacy of milk fortified with 150 Steenbock units of vitamin D per quart in the form of a cod liver oil concentrate.

min D taken daily by infants with no rickets and by those with a slight degree. The two infants with moderate rickets apparently took less than the average, though the differences are not striking. Since, however, the amount of vitamin D needed to prevent rickets depends, in all probability, on the rate of growth, further analysis of the data has been made to determine whether a relationship existed between the growth in weight and in height, the degree of rickets observed and the amount of vitamin D received. Calculations were made of the number of units taken by each infant between the first and second roentgen examinations per hundred grams of weekly gain in weight and per millimeter of weekly growth in length. Average figures were then obtained for the number of units of vitamin D taken per weekly gain in weight and growth in length by the total group of thirty-three infants and by the three subgroups arranged according to the roentgen diagnoses. Similar calculations were made of the number of units taken by each infant between subsequent examinations and the number related to age, the gain in weight, the growth in length and the diagnosis of rickets.

Table 7 shows the average number of units of vitamin D taken daily per hundred grams weekly gain in weight between successive roentgen examinations. It will be seen that in general the average number of units per hundred grams weekly gain in weight taken by those children who showed no rickets is somewhat

2 Thirty-three artificially fed infants, most of whom were under 8 weeks of age at the beginning of the study in December 1932 and two thirds of whom were Negroes or Italians, were selected for the study and were given this milk as the sole source of vitamin D. They were observed over periods of from three to six months, the last examination having been made in May

received showed that, though the infants who developed slight rickets grew somewhat faster than did those who remained normal, they nevertheless did not receive on the average more milk daily or more vitamin D. Moreover, the two infants who developed moderate rickets not only took less milk daily than did the group as a whole but also grew considerably faster. Further-

* Figured for periods of approximately four to six weeks immediately preceding the second and each subsequent roentgen examination. Infants arranged according to maximum degree of rickets found by roentgen examination during period of observation.
† One child did not gain.
‡ Two children did not gain.

3 Of the thirty-three infants fourteen remained normal, seventeen developed slight rickets during the period of observation and two a moderate degree of rickets. These diagnoses were made from roentgenograms taken at monthly intervals during the study.

4 Analysis of the data that had to do with the degree of rickets observed, the growth in weight and length and the amount of milk and hence of vitamin D

more, when the number of units of vitamin D taken daily per hundred grams of weekly gain in weight was correlated with the degree of rickets, it was found that the average number of units taken by the nonrachitic infants was somewhat greater than the average number taken by those who showed slight rickets and considerably greater than the number taken daily by the two infants who developed moderate rickets.

5 Coincident with a slowing in the rate of growth and an increase in the amount of milk consumed by these two infants there occurred an increase in the number of units of vitamin D taken daily per hundred grams of weekly gain in weight and, as a result, healing of the rachitic process took place

CONCLUSIONS

Since the amount of vitamin D necessary to prevent rickets is probably dependent to a great extent on rate of growth and since the growth of young infants does not necessarily conform to the amount of milk consumed daily, it is clear that infants who gain rapidly on relatively small amounts of milk will not receive an adequate amount of vitamin D from a fortified milk unless the amount of vitamin incorporated per quart is such that protection will be afforded when considerably less than a quart is consumed. If, therefore, milk is to be relied on for the sole supply of vitamin D during the period of most rapid growth, it would appear that the minimum amount likely to be consumed during the first four months of life—approximately a pint—should contain an amount of vitamin D adequate to protect the normal rapidly growing infant. It would appear from the data here presented that the addition to one quart of milk of 150 Steenbock units of the vitamin D concentrate used did not furnish enough vitamin D to prevent the development of a moderate degree of rickets in two out of the thirty-three infants studied. How many units of this vitamin D concentrate per quart would be required to protect completely all normal infants can be determined only by further study

DETERMINATION WHETHER KETONURINE HAS BACTERICIDAL ACTION

A SIMPLE TECHNIC FOR CLINICAL USE

ARNOLD E. OSTERBERG, PH.D.

AND

HENRY F. HELMHOLZ, M.D.

ROCHESTER, MINN.

In a previous paper we reported, from chemical and bacteriologic data, that a minimal standard of p_H and concentration of beta-hydroxybutyric acid could be set up for a ketonurine, and that if ketonurine met this standard it might be expected that it would prove to be bactericidal. These standards are a p_H of 5.5 or less and a concentration of beta-hydroxybutyric acid of 0.5 per cent or greater. If these conditions are fulfilled, the urine is bactericidal to numerous strains of colon bacilli. If this standard is exceeded by a decrease in p_H value or an increase in concentration of beta-hydroxybutyric acid, or both, it may be expected that the bactericidal action will be greater and the urine will be rendered sterile in a shorter length of time. The previous work involved the determination of the p_H value of urine by ordinary colorimetric procedures and the determination of beta-hydroxybutyric acid by the somewhat tedious, van Slyke, gravimetric procedure. Obviously, it is to be desired that a simple procedure be made available whereby the clinician can determine easily whether or not this standard has been reached or exceeded. A technic by which one can determine this is presented

The colorimetric determination of the p_H is simple and perhaps needs no further simplification, since this determination is commonly used. However, it can be determined whether or not the p_H of the urine is 5.5 or less even more simply by the use of chlorphenol red paper. Filter paper of good grade that has been soaked in an aqueous solution of chlorphenol red of a concentration of 0.04 per cent, and then dried, becomes yellow. Such a test paper will turn red at a p_H above 5.5. Hence, for determining whether the p_H of the urine is less than 5.5, it is necessary only to see that

such paper, when wetted with the urine, retains its yellow color. At the borderline of p_H 5.5 a slight orange tint may be present, but if the p_H is greater than this a distinct red is produced. Consequently it is necessary only that the urine shall not be capable of turning the test paper red, thus will insure that the standard of p_H has been reached and that the p_H of the urine is sufficiently low for bactericidal action, if the concentration of beta-hydroxybutyric acid is 0.5 per cent or more.

There is no easy, satisfactory specific colorimetric reaction for beta-hydroxybutyric acid. Hence, like Fuller, we deemed it necessary to adapt a simple procedure for determining the concentration of diacetic acid and, indirectly, of beta-hydroxybutyric acid. That there is a fairly constant ratio between the concentration of diacetic acid and beta-hydroxybutyric acid in ketonurine, over a fairly wide degree of ketosis, is shown in the tables.

In table 1 it may be noted that, for concentrations of beta-hydroxybutyric acid ranging from 0.31 to 1.97 per cent, the percentage of total acetone bodies present as beta-hydroxybutyric acid remains at the fairly constant value of from 80 to 90 per cent. Likewise, another series of cases (table 2) demonstrates that a concentration of acetone and diacetic acid of approximately 0.1 per cent accompanies a concentration of beta-hydroxybutyric acid of 0.5 per cent. Also, determinations of acetone bodies, other than beta-hydroxybutyric acid, which are present in ketonurine that contains 0.5 per cent beta-hydroxybutyric acid, demonstrate that acetone and diacetic acid are present in a concentration of 0.1 per cent, of which 75 per cent is present as diacetic acid.

In the Rothera test, diacetic acid develops approximately five times the depth of color developed by acetone, hence, the amount of color developed by ketonurine that contains 0.5 per cent beta-hydroxybutyric acid will approximate the color produced by a 0.5 per cent solution of acetone. The problem arises then, to adapt the nitroprusside reaction so that it may be performed simply and quickly. Fuller has used, as

a standard, a combination of dyes that give a color approximating that produced by acetone and sodium nitroprusside. The procedure to be described here utilizes the fact that a phosphate buffer of p_H 8.0, when treated with a mixture of phenol red and bromthymol blue in the proper concentration, produces a stable color identical with that produced by ketonurine, which contains 0.5 per cent beta-hydroxybutyric acid when treated with sodium nitroprusside.

METHOD

To 800 mg of ammonium sulphate in the ordinary Nessler comparison tube¹ graduated at 50 cc is added 3 drops of concentrated ammonium hydroxide (0.15 cc), 2 drops (0.10 cc) of a 5 per cent solution of sodium nitroprusside, and 1 cc of the urine to be examined. This is allowed to stand six minutes at a room temperature of approximately 25 C (77 F). The reaction product is then quickly diluted with water to the 50 cc mark and mixed. This solution is immediately compared with the standard. If the color of the unknown is deeper than that of the standard, the concentration of beta-hydroxybutyric acid is greater

TABLE 2—Relationship of Concentration of Acetone and Diacetic Acid to Concentration of Beta-Hydroxybutyric Acid in Ketonurine (Series 2)

Case	Beta Hydroxybutyric Acid per Cent (van Slyke Method)	Acetone and Diacetic Acid Calculated as Acetone (per Cent)
1	0.14	0.03
2	0.19	0.07
3	0.26	0.06
4	0.31	0.07
5	0.34	0.05
6	0.35	0.07

8	0.50	0.09
9	1.33	0.14
10	1.64	0.17

than 0.5 per cent. If the color is lighter, the reverse is true. The standard is prepared by adding 40 cc of a solution, containing 2 parts of 0.04 per cent solution of phenol red and 14 part of a 0.04 per cent solution of bromthymol blue, to 46 cc of phosphate buffer at p_H 8.0. The standard retains its color for a considerable time, but a fresh standard may be prepared very easily if only an occasional determination is to be made. If one desires to estimate the percentage of the beta-hydroxybutyric acid, rather than simply to determine whether or not the percentage of beta-hydroxybutyric acid is greater or less than 0.5, a series of standards can be made by adding more or less solution of dye. These standards may correspond, for example, to solutions of beta-hydroxybutyric acid of 0.4 per cent, 0.5 per cent, 0.6 per cent and so on, or the unknown may be matched in a colorimeter against the standard and the concentration of beta-hydroxybutyric acid determined by simple calculation. The color produced by acetone and diacetic acid, with sodium nitroprusside, is transient, hence, it is necessary that the color comparison with the standard be made immediately following the six minutes given for the development of color and subsequent dilution. This fact militates against the employment of a comparison in a colorimeter. If many specimens of urine are to be examined, it is necessary that a time sequence be followed, so that the diluted nitroprusside solution is not allowed to stand. Six minutes has been determined as an optimal time for the

development of color at room temperature. Only a certain maximal depth of color can be developed under the conditions of this test. This color corresponds to a concentration of beta-hydroxybutyric acid slightly greater than 0.5 per cent. Hence, when a ketonurine is obtained in which a color develops that approximately corresponds to the standard or that is slightly deeper, it is best to repeat the test on a specimen of the urine which has been diluted with an equal amount of water. If the color developed by 1 cc of urine that has been diluted 1:1 with water is again approximately as deep as the standard, it is certain that the concentration of beta-hydroxybutyric acid is about 1 per cent. Similarly, a dilution of urine 1:2 and 1:3 would indicate concentrations of 1.5 and 2 per cent if the color developed still approximated that of the standard. The highest percentage of beta-hydroxybutyric acid obtained so far was 2.57 per cent. More recent experiments have shown that many of various organisms found in urinary infection are resistant to the bactericidal action of ketonurine. Further work is being carried out to determine the concentration of beta-hydroxybutyric acid necessary for therapeutic action in such infections.

SOLUTIONS

The solutions required are (1) sodium nitroprusside, 5 per cent (this solution is not particularly stable in air, although in a well stoppered bottle it will keep for several days), (2) concentrated ammonium hydroxide, with a specific gravity of 0.88, (3) indicator, which is made by adding 28 cc of 0.04 per cent solution of bromthymol blue to 4 cc of a 0.04 per cent solution of phenol red (the solutions of dye are prepared according to the procedure given by Clark for indicator solutions), and (4) phosphate buffer solution of p_H 8.0, which is prepared according to the procedure given by Clark. 5 cc of fifteenth-molecular secondary sodium phosphate ($Na_2HPO_4 \cdot 2H_2O$) and 95 cc of fifteenth molecular primary potassium phosphate (KH_2PO_4).

SUMMARY

The fact has previously been established that ketonurine with a p_H value of 5.5, or less, and a concentration of beta-hydroxybutyric acid of 0.5 per cent, or greater, will have a bactericidal action to the commonly encountered strains of *Escherichia coli* found in infections of the urinary tract. By the utilization of chlorophenol red test paper it can easily be determined that the p_H value of urine is greater or less than 5.5. The conditions have been described for determining, by a simple qualitative procedure, whether or not ketonurine possesses a concentration of beta-hydroxybutyric acid greater or less than 0.5 per cent. This procedure utilizes the nitroprusside test for acetone and diacetic acid and the fact that a fairly constant ratio exists between the concentration of total acetone bodies and beta-hydroxybutyric acid in ketonurine.

Graham Lusk's Student Days—The first summer that I spent there (Munich) I lived on the Karlstrasse, having taken a room above a beer hall at five dollars a month. The good frau who rented the room gave me a roll without butter and a cup of coffee in the morning for five cents. I well remember the ceremony of moving from one lodging to another. A dienstman brought a small hand cart. On this were placed my worldly goods, including my books and my beer mugs. While escorting this picturesque vehicle I met Mr. and Mrs. Henry Holt, old family friends, who had a hearty laugh over the scene.—Quoted by Light, A. E. *Yale J. Biol. & Med.* 6:487 (May) 1934.

PREGNANCY AFTER PARALYSIS

REPORT OF THREE CASES

H HUDNALL WARE JR, MD
RICHMOND, VA

Paralysis occurring late in pregnancy is not infrequent, but a fairly comprehensive review of the current literature revealed the reports of only three cases. I have found no report of pregnancy occurring in a patient with paralysis of long standing.

Pregnancy occurring after paraplegia is rare. Because of the infrequency of pregnancy in this type of patient, three cases are herewith reported.

A case of spinal cord tumor simulating acute myelitis associated with optic neuritis and painless labor was reported by Dr E W Taylor¹ of Boston in 1906. This patient's symptoms occurred during pregnancy. She was delivered at term from below instrumentally because of weak uterine contractions. The delivery was painless and the convalescence normal, but death occurred a few months later.

The case of a woman seven months pregnant, paralyzed by a bullet wound of the spinal cord at the level of the fourth dorsal vertebra, was reported by Good² in 1924. He also reviewed the literature on the subject. In the case reported the patient was wounded during the seventh month of pregnancy but did not go into labor until the ninth month. She had no pains, scarcely any warning, and a precipitate delivery of a 4 pound 3 ounce (1,900 Gm) baby. Eight days later phlebitis of the left leg developed and sixteen days post partum a rash appeared on the body which was diagnosed scarlet fever. She died about five weeks after delivery.

Another case presenting pachymeningitis and painless delivery from below was reported by Lewis.³ Later, a laminectomy was performed on this woman. She recovered, with no paralysis, and has since had children and normal labor pains.

Warren⁴ determined experimentally in guinea-pigs that a uterine incision heals normally after the cord has been severed in the region of the second and third thoracic vertebrae.

REPORT OF CASES

In the following three cases delivery was done by me.

CASE 1—Mrs M V S, a white woman, aged 30, a primigravida, was admitted to the Memorial Hospital, Jan 17, 1933. She was referred by Dr Phipps of Hopewell, Va, because of pregnancy of thirty-seven weeks' duration occurring three years after complete motor and sensory paralysis below the nipple line.

She had the usual diseases of childhood. The past history was otherwise essentially negative until the occurrence of paralysis in 1930, three years before pregnancy.

The menses commenced at the age of 15 years and occurred every twenty-eight days, of from four to six days' duration with severe pain until paralysis in 1930, after which the periods were regular but painless. Her last menstrual period began May 4, 1932.

Early in February 1930 she had 'influenza' and remained in bed about two weeks. One week later she noticed a weakness in the lower extremities, which gradually ascended, and

seven days later the paralysis involved her arms and she was blind in both eyes. She gradually improved, and three months later her vision was good and she had regained the use of her arms and hands. Her condition has otherwise remained unchanged, with complete motor and sensory paralysis below the second dorsal segment of the cord. There was incontinence of urine and feces, and the patient stated that sexual intercourse caused no sensation.

The patient stated that she had no discomfort during pregnancy and did not realize her condition until several months after her last menstrual period.

On physical examination the abdomen was enlarged to the size of an eight months' pregnancy. The abdominal muscles were flabby. There was no abnormal tenderness or rigidity. The fundus of the uterus measured 35 cm. The fetus presented as a frank breech in the left sacro-anterior position. Fetal heart sounds were present.

There was marked atrophy of the muscles of both lower extremities.

Pelvic measurements were within normal limits. The cervix was closed and the buttocks of the baby presented above the pelvic inlet.

The patient was examined by Dr Lysterly of the neuro-surgical department, who reported complete flaccid paralysis of both lower extremities, with complete loss of sensation below the first or second dorsal segment of the cord and loss of reflexes in both lower extremities. A lumbar puncture showed spinal fluid pressure of 100 mm of water.

The Queckenstedt test was done with the patient quiet and relaxed. The spinal fluid pressure rose to 200 mm of water in ten seconds and fell immediately to 110 mm of water after release of the jugular compression.

Roentgen examination showed no evidence of pathologic changes except a congenital fusion of the second and third cervical vertebrae.

The laboratory examination showed erythrocytes, 4,800,000, hemoglobin, 80 per cent, leukocytes, 8,800. The Wassermann reaction was negative. A catheterized specimen of urine contained 1 plus albumin, many bacteria and an occasional pus cell but otherwise it was normal.

Because of the marked atrophy of the abdominal muscles and the size and position of the fetus, it was decided to deliver the patient by cesarean section and to sterilize her by excision of the cornual ends of both fallopian tubes.

The patient was delivered by elective low cesarean section January 28. No anesthesia was necessary and the patient had no discomfort at any time during the operation. The baby a girl, weighed 7 pounds and 5 ounces (3,317 Gm), it was normal and in good condition.

There was no abdominal distention or discomfort after the operation. The temperature remained normal until seven days post partum, when it gradually became elevated and at one reading on the tenth day was 101.8 F, after the twelfth day it was below 100, after the sixteenth it remained normal.

At the onset of the septic temperature, slight edema of the left foot and leg was noticed. The edema disappeared after ten days, and no other evidence of phlebitis was observed.

The lochia was normal for a post cesarean section case. The patient's breasts never became engorged or showed evidence of lactation. The baby was artificially fed.

The abdominal incision healed by primary union and both mother and child were discharged from the hospital, February 23, in good condition.

CASE 2—Mrs M C, a white woman aged 27, was attended at home. She was seen by me Feb 17, 1933, when about seven months pregnant. Her last menstrual period commenced July 6, 1932, and lasted five days.

She had had the usual diseases of childhood but the past history was otherwise negative until 1929, when she was injured in an automobile accident, suffering a fracture dislocation of the first lumbar vertebra. A laminectomy of the eleventh and twelfth thoracic and first and second dorsal vertebrae was done to relieve the pressure on the cord. There was a septic temperature during the first two weeks after operation probably caused by 'cystitis.' The operative incision healed by primary union but the paralysis remained approximately the same.

From the Department of Obstetrics, Medical College of Virginia.
Read before Medical College of Virginia Staff Meeting Dec 14, 1933.

3 Lewis. Dean in discussion on Good. J A M A 83: 418 (Aug 9) 1924.

4 Warren. Shield quoted by Good.

The menses commenced at the age of 13 years and occurred regularly every twenty-eight days, lasting five days, with no pain. She became pregnant in July 1932, about three years after being paralyzed. The pregnancy had been uneventful except for slight nausea and occasional vomiting during the first three months.

The patient stated that she had no sensation from intercourse. She was incontinent for both urine and feces, but at times she could retain small amounts of urine in the bladder temporarily. Usually she used an indwelling catheter connected to a tube and bottle. A catheterized specimen of urine contained numerous pus cells and a trace of albumin. It was otherwise normal.

The head and neck were normal. The teeth were in fair condition. The heart and lungs were normal. The pulse was 80 and the blood pressure was 100 systolic 60 diastolic.

The abdominal muscles were flaccid. The patient was not sensitive to pin pricks below a level approximately 2 inches above the upper border of the symphysis. The abdominal muscles were relaxed and there was considerable atrophy of the muscles of the lower extremities.

The abdomen contained a tumor the size of a seven months pregnant uterus. Fetal heart sounds were loudest in the lower left quadrant of the abdomen. The vertex presented in the left occipital transverse position with the head entering the pelvis. The pelvic measurements were within normal limits.

Vaginal examination showed the perineum relaxed with loss of tone of the pelvic muscles. The cervix was closed, partially effaced and at the normal level.

The pregnancy progressed uneventfully until 9 p. m., April 7, when the membranes ruptured spontaneously and a considerable amount of fluid was lost. Weak uterine contractions commenced one hour later and occurred at fifteen minute intervals throughout the night. During the last twelve hours of labor the uterine contractions remained weak but occurred regularly every ten minutes. The patient had no pain and stated that uterine contractions caused a feeling similar to that experienced when there was gas in the intestine.

At 11 p. m., April 8 the patient had been in labor twenty-five hours. The uterine contractions which had occurred at ten minute intervals became infrequent during the last hour. The cervix had been fully dilated two hours, and the head engaged with the vertex 1 cm below the ischial spines. Delivery was completed with forceps (midforceps). No anesthesia was necessary and the patient experienced no pain but was uncomfortable from the pressure exerted on the abdominal wall when the placenta was delivered by the Crede method fifteen minutes after the baby. There was no laceration of the perineum but a slight abrasion of the posterior portion of the remaining hymenal ring. The uterus contracted normally after the third stage of labor.

The baby weighed 6 pounds and 4 ounces (2835 Gm). It was alive and apparently normal except for shortening of the bitemporal diameter, 7 cm., the biparietal diameter measured 10 cm. The shape of the head may have been due to pressure, as the fetal head entered the pelvic inlet about the seventh month as a vertex left occipital transverse presentation.

The mother made an attempt to nurse the baby, but it was unsuccessful because the breasts never filled. Convalescence was normal.

CASE 3—Mrs. I. K. M., a white woman aged 29, a sextipara, quintipara, was admitted to Memorial Hospital, June 23, 1933. Her last menstrual period commenced Nov. 13, 1932 of two days' duration.

She was referred by Dr. Carter of Boynton Va. because of pregnancy of thirty-seven weeks in a woman with paralysis of four years' duration.

During childhood she had chickenpox, measles, pertussis and erysipelas, her early history was otherwise negative.

The menstrual periods commenced at the age of 14 years, occurred every twenty-eight days and usually lasted three days. After the patient's injury in 1929 the menses were irregular for one year, but during the three years preceding the present pregnancy the periods were regular.

She was married in 1918 and had five pregnancies during the next ten years, all terminated spontaneously after normal labors. The babies all lived.

The present paralysis resulted when the patient fell from a tree in June 1929. A roentgen examination at that time showed a compressed fracture of the first lumbar vertebra and a fracture of the transverse process.

An operation was performed, June 5, 1929, by Dr. Lyster, and the laminae of the twelfth thoracic and first lumbar vertebrae were removed to relieve the pressure. There was some posterior dislocation of the body of the first lumbar vertebra and there was a spicule of bone in the spinal canal almost completely severing the cord. The rest of the cord was badly bruised and injured.

The operation was performed under local anesthesia with no pain. The incision healed by primary union. June 20, fifteen days after operation, an acute pyelitis developed which was controlled by conservative treatment.

Several weeks after she left the hospital a bed sore developed, but this later healed and, except for the paralysis below the first lumbar vertebra, her condition had been good. She states that she has had no sensation from intercourse since the onset of paralysis. She has also been incontinent for urine and feces during this time.

Physical examination revealed that she was well nourished but unable to move the hips and lower extremities.

Abdominal examination revealed sensation to pain above the symphysis and showed the uterus enlarged to the size of a thirty-six weeks pregnancy. The fundus measured 33 cm., fetal heart sounds were heard in the left lower quadrant at a rate of 160 per minute. The baby presented as a vertex left occipito anterior position, with the head not engaged.

Vaginal examination showed a relaxed perineum with loss of muscle tone, the cervix 1 cm. dilated but not effaced.

Examination of the lower extremities showed definite atrophy of the muscles.

A catheterized specimen of urine was cloudy, with a specific gravity of 1.019. It contained a trace of albumin and from 5 to 7 pus cells per high power field. It was otherwise normal. Blood examination revealed erythrocytes, 3,920,000, leukocytes, 10,200, and hemoglobin, 80 per cent. The Wassermann reaction was negative.

June 30, she was prepared for an operative delivery. A spinal puncture was made in the second lumbar interspace. Spinal fluid was obtained, and procaine crystals, 150 mg., were dissolved and injected, but the patient had anesthesia only 2 inches above the symphysis and the operation was completed under nitrous oxide and oxygen anesthesia. Evidently there was a partial obstruction of the spinal canal at the level of the injury. A low cesarean section was performed and the patient was delivered of a normal male baby that weighed 6 pounds and 2 ounces (2778 Gm). Following delivery of the placenta the uterine tone was poor, and there was free hemorrhage from the uterus. The uterine cavity was packed with gauze, which was removed from the vagina twenty-four hours later.

The temperature was 101.8 at one reading the day after operation. Thereafter it remained below 100.2, and was 98.6 most of the time. The lochia was considered normal for a postoperative patient.

The mother made an attempt to nurse the baby during the first twelve days after delivery, and the baby was put to the breast regularly, but usually it got no milk. After one period at the breast there was a gain of 1 ounce (30 Gm.), but usually there was no increase in weight and the baby was bottle fed after the twelfth day.

There was no abdominal distention but the patient was incontinent for urine and feces as she had been before operation. The abdominal incision healed by primary union and both mother and baby were discharged, July 16, sixteen days after operation.

SUMMARY AND CONCLUSIONS⁵

The following points are of interest in these cases:

1. Pregnancy can occur in paralytic women.
2. Labor is painless.

⁵ The author is indebted for valuable information to Curtis A. H. Gynecology and Obstetrics, Philadelphia W. B. Saunders Company 3-1118-1933.

3 There is absence of any instinctive use of the accessory muscles during labor

4 Uterine contractions were weak in the patient delivered from below

5 Cesarean section and sterilization should be resorted to frequently in these patients

6 Cesarean section may be performed in some cases without an anesthetic

7 The uterine and abdominal incisions heal normally

8 My patients were unable to nurse their babies

DISLOCATION OF THE SHOULDER

ACCOMPANIED BY FRACTURE OF THE GREATER TUBEROSITY AND COMPLICATED BY SPINATUS TENDON INJURY

PAUL W GREELEY, MD
WINNETKA, ILLINOIS

AND

PAUL B MAGNUSON, MD
CHICAGO

In our experience, fracture of the greater tuberosity of the humerus associated with dislocation of the head from the glenoid cavity is relatively rare. An inquiry among our colleagues appears to bear out this fact. An investigation of the literature, however, brings forth many diversified opinions. Eliason,¹ quoting Graessner, states that this type was found in twenty-four out of forty-eight cases of dislocation, and the percentage probably would be even higher if x-ray films were taken always before an attempt is made to reduce a dislocated shoulder. Roberts² collected eight cases that were seen in the Massachusetts General Hospital between 1923 and 1931. However, he does not tell how frequently fracture is associated with dislocation. Cubbins and Scuderi³ found ten instances in 500 fractures of the humerus. Gratz⁴ and Fruhmunn⁵ each report one case. Rixford⁶ states that fracture of the greater tuberosity as a complication of dislocations of the shoulder is due commonly to impingement on the edge of the glenoid, and its points of attachment of the dorsal scapular muscles often are pulled away. Moreover, he points out the fact that stereoscopic x-ray films are invaluable in diagnosis of such fractures. In discussing fractures of the greater tuberosity, Park⁷ states that it may occur in conjunction with dislocation of the shoulder. Murray⁸ reports also that fracture of the greater tuberosity sometimes occurs as a complication following dislocation of the shoulder. Nicod⁹ reports a case that was not diagnosed correctly until three months after the acci-

dent. At this time it was found necessary to do an open operation to bring about relief. McWhorter¹⁰ reports two cases of his own and quotes figures from the following authors: (1) Schlaepfer¹¹ found fracture of the greater tuberosity in eight of 120 dislocations of the shoulder; (2) Gubler¹² found this fracture to occur eighteen times in 252 dislocations. It will be noted that the last two quotations are in marked contrast with the proportions mentioned by Eliason.¹ Two more cases are reported by Csillag,¹³ which were not diagnosed until several weeks following the injury. These cases both came to open operation. One case is reported by Hodgson,¹⁴ but it was not diagnosed until after reduction of the dislocation. Meyerding,¹⁵ in a series of twenty-four shoulder dislocations, found the greater tuberosity fractured in two of them. Such figures as shown here seem to point out, with the exception of one author, that dislocation of the shoulder complicated by fracture of the greater tuberosity of the humerus is a relatively rare condition. It does occur frequently enough, however, so that it should be considered every time a dislocated shoulder is seen.

Complicating this type of fracture dislocation of the shoulder is injury to one or both of the spinatus tendons. Probably most of the existing knowledge of this condition is the result of work done by Codman. He makes first mention of theoretical injury to the spinatus tendons in a paper¹⁶ published in 1906. He has more recently stated¹⁷ that he has seen this injury 122 times and has operated in thirty-eight of these cases. He states that it occurs especially with dislocation, but he does not mention its occurrence with dislocation fracture of the greater tuberosity. In a recent study of 340 anatomic dissections, Fowler¹⁸ found complete rupture of the supraspinatus tendon in one out of every twenty-eight shoulders examined, and incomplete rupture in one out of every six shoulders.

ANATOMY AND PATHOLOGY

It will be remembered that the tendons of the supraspinatus and infraspinatus and teres minor muscles are inserted in the greater tuberosity, and these muscles as a group often are called the external rotators of the arm¹⁹ (fig 1). It is also necessary to remember²⁰ that the capsule of the shoulder joint in its superior and posterior portion blends with and becomes indistinguishable from the flat expanded tendons of the supraspinatus, infraspinatus and teres minor muscles as they pass to their points of insertion in the greater tuberosity of the humerus. These tendons blend with one another and can be differentiated only in an arbitrary manner.

The supraspinatus tendon lies superiorly and forms the roof of the shoulder joint. It also forms a part of the floor of the subacromial bursa, which is interposed between it and the acromial process and extends nearly an inch between the greater tuberosity and the deltoid muscle.

The spinatus tendon commonly ruptures close to the greater tuberosity. Retraction of the muscle enlarges the gap and creates an opening through which there is direct communication between the bursa and shoulder joint. In a series of ten cases of complete rupture studied by Wilson,²¹ this gap measured from 1 to 2½ inches in diameter, with the average measuring about 1½ inches. In addition to gross ruptures, oftentimes a small tear involving a few fibers of the tendon may occur. This lesion is probably the most common cause of traumatic subdeltoid bursitis. Calcification²² of the tendon is thought to be due to partial ruptures following which nature attempts to repair a tissue with little blood supply.

SYMPTOMS AND DIAGNOSIS

The earliest symptoms are similar to those of subluxation of the head of the humerus from the glenoid

Fig 1—Relationship of structures around shoulder joint in which there is a dislocation of the head of the humerus complicated by fracture of the greater tuberosity. (From Magnuson's *Fractures*.)

cavity. The arm hangs a little away from the side. The roundness of the shoulder has disappeared. The glenoid fossa can usually be palpated and the head of the humerus may be felt in the axilla. There is marked tenderness over the greater tuberosity, which is not found in simple dislocation. Furthermore, the patient will nearly always give a history of a direct blow against the shoulder at the time of injury.

Before one attempts any manipulation, x-ray films of the shoulder should be made, not only will these show the dislocation of the head of the humerus from the glenoid cavity, but the greater tuberosity will be found lying above and medial to its normal position.

Diagnosis of tendon injury may be quite difficult at this time, in fact it is unwise to test for its continuity now because, if it is not ruptured tension on it will tend to pull the greater tuberosity still farther out of place. Later, when bony union has occurred, the fol-

lowing picture may present itself. The patient will have difficulty in raising the arm from the side to complete abduction unless he does it with the arm in either complete internal or external rotation. There may be a tender spot over the greater tuberosity. By passively pulling the arm downward and then abducting it, the patient will complain of pain and crepitus when the greater tuberosity slides beneath the acromial process. Active external rotation may be impossible or diminished. X-ray films taken of old cases frequently reveal a hypertrophy or roughening of the greater tuberosity. If sufficient time has elapsed, atrophy of the suprascapular muscles may be seen. Fowler²³ describes his test for rupture of the supraspinatus tendon as follows:

The patient rests his shoulder on a crutch or upon a comfortable high back chair so that the shoulder is elevated 2 to 3 inches thus relaxing the trapezius muscle. The patient is asked to abduct the dependent arm a number of times with the examiner's fingers resting on the relaxed trapezius directly over the supraspinatus muscle. If the tendon is ruptured there will be an absence of palpable contraction of the supraspinatus muscle on the affected side. The infraspinatus can be felt and even seen in most cases without special position of the shoulder. Snapping or crepitation is often heard and felt by the patient, and sometimes all those present at the examination, when the greater tuberosity passes beneath the acromion process.

TREATMENT

The treatment of dislocation of the shoulder with fracture of the greater tuberosity is usually quite simple. The dislocation is readily reduced by the Kocher method, preferable under general anesthesia. As the shoulder is replaced in the glenoid cavity, it slides against the fragment of the greater tuberosity and it too falls into perfect position. In view of the anatomy involved, the arm should then be put up in abduction and external rotation so that there may be no tension on the greater tuberosity. It should be kept in this position for from three to four weeks, after which it may be let down to the side and some type of physical therapy carried out until the function has well returned. It is doubtful whether open reduction for replacement of the tuberosity is ever necessary. To illustrate this point, Roberts² tells of one case in his series. The attending physician was dissatisfied with the postreduction x-ray films, so he decided to do an open operation with the idea in mind to fix the greater tuberosity with fascia or a bone peg. However when the region was exposed the tuberosity was found to be in such good position that the wound was closed and he stopped looking at the x-ray films. Cubbins and Scuderi³ found "much to their amusement" that in some of their cases the greater tuberosity remained in good position even though the arm was placed along the thorax in a Velpeau bandage. This may be adequate in selected cases but we feel that there is no definite criteria on which to base selection except an x-ray film. Of course, this shows only the bony injury and does not give one any conception of how much or how extensive the associated capsule injury may be. Hence we feel that it is better to err on the side of safety and treat all these injuries as more than a simple fracture. This is, of course, best carried out by placing the arm in abduction and external rotation.

The treatment of the tendon injuries is much more complicated. If the rupture has been only partial, the relaxation of the muscles incident to the treatment of

the bone injury by abduction and external rotation usually will be adequate to permit complete healing of the tear. If, however, a complete rupture of one or more tendons can be diagnosed, early open operation should be done. It is also wise in case of doubt to make a small exploratory incision to make sure that some injury is not overlooked. The operation itself consists

no limitation of motion, pain, tenderness or crepitation following, so a diagnosis of tendon injury was impossible. At the present time, two and one-half years later, he has a perfect result.

CASE 2—Mrs. P. E., aged 58, was seen shortly after falling against her right shoulder on a recently waxed floor. There was immediate pain, deformity, and marked tenderness over the outer border of the head of the humerus. X-ray films showed a downward dislocation of the head of the humerus with fracture of the greater tuberosity. The patient was anesthetized with nitrous oxide gas, which was changed to drop ether in order to gain satisfactory muscle relaxation. The shoulder was then replaced by the Kocher maneuvers. Post reduction roentgenograms revealed perfect reduction of the head and replacement of the greater tuberosity. The patient was then placed in an airplane splint with the arm in 90-degree abduction and complete external rotation.

The patient did not tolerate the airplane splint at all well because of the fact that she was short in height and weighed over 200 pounds. After two days the splint was removed and the patient put to bed on her back. The arm was held in abduction and external rotation by light sand bags. This position was maintained for two weeks, after which the patient was allowed up wearing a sling. Gentle physical therapy followed and three weeks from the time of injury all support was discontinued. External heat and massage were continued for six weeks more. The patient then had perfect use of the shoulder, without pain. At the present writing, nearly three years after the accident, the injured shoulder appears in all respects to be as good as the other.

CASE 3—Mrs. E. K., aged 36, was thrown from a horse. She struck against her left shoulder and had immediate pain, disability and deformity. X-ray films showed a downward and forward dislocation of the head of the humerus and a comminuted fracture of the greater tuberosity. Under nitrous oxide gas, the shoulder was reduced by the Kocher method without difficulty. Roentgenograms taken immediately afterward showed a perfect reduction of the head and also the fragments of the greater tuberosity. An airplane splint was applied with the arm in complete abduction and external rotation. This splint was worn for three weeks, after which a sling was worn for one week more.

RESULTS

Cases in which operation is performed relatively early result in perfectly useful joints. However, the old cases may present so much muscle atrophy and tendon shortening that there may be some limitation of internal rotation and abduction of the humerus. The latter may also be accompanied by some pain.

REPORT OF CASES

To illustrate the foregoing discussion, the following cases taken from our experience may serve well as examples.

CASE 1—E. T., a man aged 22, was seen within half an hour after an accident. He had been playing tennis and, while running for a ball, he tripped and fell with his shoulder against the net post. Immediate pain, deformity and disability of the shoulder resulted. Roentgenograms taken soon afterward revealed a subglenoid dislocation of the head of the humerus with a displaced fracture of the greater tuberosity (fig. 2). The patient was anesthetized with nitrous oxide gas and the dislocation reduced by the Kocher method. A film after reduction (fig. 3) showed the head in the glenoid fossa and the greater tuberosity back in perfect place on the humerus. The arm was placed in an airplane splint in 90 degree abduction and complete external rotation for three weeks following which it was let down and a sling worn for four days. Following the removal of the splint, external heat, massage and passive motion were carried out daily for one week after which it was done three times weekly for the next two weeks. There was

Fig. 2 (case 1)—Subglenoid dislocation of head of humerus with displaced fracture of greater tuberosity.

Fig. 3 (case 1)—After reduction head in glenoid fossa and greater tuberosity in place.

The patient had far more shoulder pain after the reduction than the other two patients, enough so that further injury should have been suspected. Beginning two weeks after the accident, diathermy treatments were given to the shoulder every other day. Other forms of physical therapy were continued for nearly three months because of pain and limitation of motion. By this time it was obvious that there was still some other derangement of the joint present. There was ten-

derness on pressure over the greater tuberosity. As the patient was very slender, there was no apparent atrophy of the suprascapular muscles. She could not have the arm abducted actively or passively more than 45 degrees from her side because of an apparent blocking of the greater tuberosity against the acromion. If, however, the arm was rotated either internally or externally it could then be abducted to 90 degrees but only with pain and crepitation when the edge of the greater tuberosity passed beneath the acromion process. The arm could also be completely abducted from the side if it was pulled downward during the maneuver so as to overcome the upward pull of the deltoid muscle. Roentgenograms at this time showed some enlargement of the greater tuberosity, otherwise the bones of the shoulder were normal. In view of the continued pain and disability and the presence of the conditions noted it was decided to explore the region of the greater tuberosity.

Under ethylene anesthesia the shoulder was opened. Both the supraspinatus and infraspinatus tendons were found to be pulled from their normal attachment and the ends were located attached three-fourths inch posteriorly. With the arm held in complete abduction and external rotation the tendon ends were loosened and pulled down and sutured to the posterior border of the distal end of the subscapularis tendon with chromic catgut. The wound was then closed and the patient put in bed with her arm fastened down in 90-degree abduction and complete external rotation. This position was maintained in bed for two weeks after which she was allowed up and an airplane splint was applied still maintaining the same position. This brace was worn for four weeks. Physical therapy was begun three weeks after the operation and continued for two months.

At present over two years after the original injury the patient has perfect use of the shoulder. There is no pain except that sometimes in certain positions a slight click is felt when the greater tuberosity passes beneath the acromion. This click is occasionally accompanied by a slight wincing pain.

CASE 4—A woman had a subglenoid dislocation of the head of the humerus which was already properly reduced when she came under our care. She presented a marked swelling of the shoulder joint much more than one would usually see accompanying a dislocation. The first x-ray film taken with the arm in abduction and internal rotation gave normal results. Another film was then taken with the arm in external rotation to show the trochanter in profile. We found the greater tuberosity to be roughened and to be irregular on the tip and finally managed to make out the thin shell of bone from the torn tendinous attachments lying above it, between the head of the humerus and the acromion. The arm was put up in 75-degree abduction with the elbow forward level with the anterior chest wall, and the arm in external rotation. There was a complete recovery in three months.

CASE 5—This was the result of a fall on the outstretched arm to the side with a continuation of the force so that the hand traveled above the head and backward. In other words this patient pitched toward the right side and the hand was carried upward and backward by the continuing force. There was a dislocation of the humerus but it seems likely that in this case there was direct violence to the greater tuberosity by the end of the acromion before the head was dislocated. This point is, of course, theoretical. There was no difficulty in maintaining this fragment in position with 60 degrees of abduction. The patient made a good recovery.

CONCLUSIONS

1 Fracture of the greater tuberosity sometimes occurs when the head of the humerus is dislocated from the glenoid fossa. These fractures may be overlooked unless roentgenograms are taken with the arm in external rotation so as to show the trochanter in profile.

2 Since fracture of the greater tuberosity may accompany dislocations of the shoulder, it is imperative that x-ray films be made before an attempt is made to reduce any such injury. If a fracture exists, post-reduction roentgenograms should follow.

3 Tearing of one or both spinatus tendons may accompany dislocation of the shoulder when the greater

tuberosity is simultaneously fractured. One should attempt to diagnose this complication as soon as possible so as to institute an early repair if a good end result is to be expected.

GASTRO-ENTEROSTOMY WITH EXCLUSION OF INOPERABLE CANCER OF PYLORUS AND ANTRUM

GEORGE T. PACK, MD

AND

ISABEL M. SCHARNAGEL, MD

NEW YORK

Gastro-enterostomy with exclusion of cancer of the pylorus and antrum may be the first step in a two stage resection or may be indicated as a palliative measure for inoperable cancers of this location. The advantages and technique of this operation are presented here, with a review of the evolution of this procedure.

The treatment of choice for operable gastric carcinoma is resection of the stomach. This procedure is not tolerated well by patients in poor general condition with tumors of questionable operability because of fixation, surrounding inflammatory reaction and enlarged perigastric nodes. We have previously explained the advantages and indications for using two stages in resections under these conditions.¹ The first stage, consisting of exclusion of the carcinomatous segment of the stomach with gastro-enterostomy, may be done under a local anesthetic and requires little more time than gastro-enterostomy alone. The patient receives a liberal postoperative diet so that he is better able to tolerate the second stage of the operation or removal of the tumor, which is quickly and safely done with a functioning gastro-enterostomy. The second operation is less often complicated by infection, as the peritoneum seems to acquire an immunity through the contamination of the first operation. The danger of infection extending by way of the lymphatics through the diaphragm has been mentioned as more imminent in carcinoma than in ulcer of the stomach. We have found that the inflammatory reaction about the tumor will subside after it has been freed from contact with the gastric contents so that this segment of the stomach may be more easily dissected from the surrounding organs. The perigastric nodes may also diminish markedly in size, proving their inflammatory nature. During the entire management there is no interruption in feeding the patient. Balfour² advised the selective use of this two-stage operation in 1928. The first stage may be gastro-enterostomy alone or gastro-enterostomy with exclusion of the cancer-bearing pyloric segment of the stomach.

The latter procedure has had frequent application in our hands as a palliative measure for inoperable cancers of the pylorus and antrum, in which the second stage or removal of the tumor is not planned. Gastro-enterostomy alone has been the procedure in these cases previously. Gastro-enterostomy for cancer is attended

by a mortality rate that is almost as high as for gastric resection and in addition has many other disadvantages, which we shall summarize briefly. W H Mayo has aptly said that gastro-enterostomy for cancer enables the patient to live longer and suffer more. The symptomatic relief from this operation is not great, as the patients continue to experience some pain, anorexia, nausea and frequent eructation of gas and foul liquid. The food is contaminated by contact with the ulcerated infected lesion. The tumor is irritated by the food and products of digestion resulting in continued bleeding and progressive anemia. The infected cancer may delay the healing of the wound of anastomosis and lead to perforation. The carcinoma after gastro-enterostomy frequently grows upward to involve and obstruct the stoma, unless a very high anastomosis is done, in which case it is not of great aid in emptying the stomach. Even with a gastro-enterostomy, the peristaltic waves attempt to force the food through the pylorus and past the obstructing cancer. Kelling³ has shown that, after gastro-enterostomy, 235 of 250 cc of fluid introduced into the stomach passed through the unobstructed pylorus, while only 11 cc passed through the gastro-enterostomy stoma. This work was verified by

The advantages of gastro-enterostomy are greatly enhanced by permanent exclusion of the carcinoma of the pylorus, antrum and occasionally pars media, from the uninvolved proximal segment. The first case in which we employed this procedure was an inoperable carcinoma of the first part of the duodenum. This operation is done in one stage for inoperable cancers only. Its chief indication is when the carcinoma is so fixed and adherent that partial gastrectomy is not feasible. We employ partial gastrectomy for palliation even in the presence of metastases to the liver or

Fig 1—Evolution of methods of excluding pylorus for ulcer and carcinoma. The technical details are described in the text.

Lewisohn⁴ who derived his opinion through the use of a dye, thionine blue, which has an affinity for mucus. Pyloric obstruction will deflect more of the gastric contents through the gastro-enterostomy stoma, nevertheless the carcinoma in this segment of the stomach continues to be traumatized so long as it remains in the gastro intestinal channel.

Fig 2—First step in the exclusion of an inoperable carcinoma of the pylorus.

supraclavicular nodes if the patient is in good condition and the stomach is sufficiently mobile.

The operation we are describing in this communication is not to be generally used, but it is helpful in indicated cases. Its purpose is to prolong life and to make the patient more comfortable. It may also precede palliative irradiation when there is retention of the barium ingesta at the end of six hours, external and interstitial irradiation may be more safely employed, as there is less danger of infection and perforation of the cancer as well as injury to contiguous mucous membrane. This operation has a lower mortality rate than gastro-enterostomy alone, as has been proved statistically by several authors, who used various methods of exclusion for gastric and duodenal ulcer. The excluded distal segment of the stomach is put at complete rest, which greatly relieves pain and discomfort. The appetite and digestion improve as soon as the proximal gastric mucosa becomes clean and free from infection. The tumor itself becomes smaller, presumably because of the subsidence of infection and surrounding inflammatory reaction. This is beneficial in three different ways. Irradiation is not handicapped by the diminished radiosensitivity of the cancer which infection entails, the rate of growth of the tumor is no longer increased by the stimulation through infection, the exclusion of digestive ferments renders the danger of autodigestion and perforation of the cancer less imminent. Hemorrhage is then an infrequent com-

plication and the anemia less fulminating. Exclusion of the tumor prevents its extension to involve the new stoma and occasionally the cardia.

Exclusion of the pylorus or distal third of the stomach for gastric and duodenal ulcers has been advocated by innumerable surgeons during the past forty years. We have not attempted to cull a complete bibliography from the literature on this subject but have shown diagrammatically the salient features of these operations in figure 1. The majority of these authors have applied this operation only in the treatment of peptic ulcers, Parlavacchio⁵ in 1910 being the only one we discovered who used it for carcinoma. We claim no originality for this procedure. It is presented here because its advantages are not well recognized.

The first operation for exclusion of the pylorus was described by Doyen in 1892 and was accomplished by means of a transverse section of the stomach with blind closure of the ends. Three years later, von Eiselsberg⁶ described a similar procedure which he advised for the surgical treatment of peptic ulcers in preference to simple gastro-enterostomy. His technic will later be described in full. This operation in the hands of its originator required about ninety minutes. Its value in the treatment of selected cases with ulcers of the duodenum and pylorus as well as some situated high on the lesser curvature was recognized and stimulated surgeons to seek simpler methods for obtaining the same benefits. We shall describe a few of these procedures to illustrate the evolution of the operation.

Girard⁷ in 1900 devised a plastic operation for constricting the pylorus, which was a reversal of the Hemcke-Mikulicz pyloroplasty. The Hemcke-Mikulicz pyloroplasty, which is used to relieve pyloric obstruction due to cicatricial narrowing, is performed by making a longitudinal incision through the anterior gastric wall directly over the pylorus, extending 1 inch onto

anterior wall of the antrum proximal to the ulcer or pylorus (if duodenal ulcer) and approximated the ends and sides of the incised wall in a longitudinal direction. This method never became popular. Kelling and Mayo⁸ in 1904 attempted to close the lumen of the pyloric segment by means of four ligatures of silver wire, each of which was stitched twice

Fig. 4.—Functioning gastro-enterostomy. The silver clips (von Pets) marking the location of the severed distal segment of the stomach are at the margin of the vertebral shadow.

through the wall and then tied so as to produce an infolding of the wall. This method did not give permanent results, as proved by the postmortem examination of a patient so treated.

Kelling in 1899, Berg⁹ in 1903 and Cackovic¹⁰ in 1903 described simple methods of ligating the pylorus with Pagenstecher sutures. Wilms used a free autoplasmic transplant, usually of fascia lata, for a constricting band. Parlavacchio in 1910, evidently without knowledge of the previous methods, attempted to ligate either near the pylorus or higher by means of a constricting band of cotton tape. He advised this procedure for pyloric or prepyloric cancer, giving excellent reasons for its use. He first tried animal experiments and did not report its use in human beings until 1913. Wynen¹¹ in 1927 reported the use of a mattress suture to exclude the pylorus experimentally but concluded that it did not produce a permanent obstruction. This is true of all ligation methods.

Biondi in 1913 devised a method intermediate in degree between the simple ligation technic and the more extensive operative procedure of von Eiselsberg. He made a longitudinal incision including only the seromuscular layers of the anterior wall of the antrum and extending to the pylorus. The mucosa was then

Fig. 5.—Diagram of completed operation for exclusion of inoperable cancer of the pylorus with isoperistaltic gastro-enterostomy.

the antrum and duodenum. The oral and aboral ends are then approximated and a transverse closure is made in two layers. Girard made a transverse incision in the

dissected free, ligated twice and severed between the ligatures. The incised layers were sutured, leaving an exclusion which was permanent.

In 1914 Bartlett¹² described a similar method, which did not require a complete transverse section of the stomach. This procedure, also known as "Hammersfahr's subserous method," was modified by Burkhardt¹³ in 1922. Its object was to build a septum above the pylorus. The transverse incision was made through the entire thickness of the anterior gastric wall but only through the posterior mucosa. In other words the mucosal layer was completely severed with only the posterior seromuscular layer of the stomach intact. The proximal anterior and posterior mucosal layers were inverted and sutured, as were the distal layers. The anterior seromuscular layers were then sutured to the intact posterior layer.

Lewisohn¹⁴ classified and summarized these methods concluding that simpler measures were as satisfactory for peptic ulcer as the more complicated procedures.

Finsterer¹⁵ used a technic which does not seem to differ from that of von Eiselsberg except in the variation of the level for section of the stomach and the completion of the operation in one case by a terminolateral anastomosis between the proximal segment and the duodenum. Devine¹⁶ used a similar procedure, always establishing continuity of the lumen by means of a terminolateral anastomosis. He also made a deep incision into the gastrohepatic omentum, into which he sutured the closed pyloric end in order to aid drainage. In a later article he¹⁷ reported a case in which a jejunal ulcer, developing after a gastro-enterostomy, was isolated by division of the stomach above the stoma and anastomosis of the jejunum to the proximal segment side to end, thus eliminating the jejunal ulcer in the segment between the two sutured portions. A lateral entero-anastomosis was done to drain the distal closed loop of duodenum and pylorus.

Bancroft¹⁸ sectioned the stomach without a clamp on the distal portion, dissected the mucosa free in the segment of the stomach, then ligated it at the pylorus and removed the excess to prevent stasis in the blind pouch. Cunningham¹⁹ showed by animal experiments that this procedure was unnecessary. He performed partial and subtotal pyloric exclusion operations on dogs and found that the excluded portion contracted to form a tube with the cut surface lying horizontally and the mucosa degenerated. The parietal cells degenerated to a greater extent than the chief cells and were replaced by fibrous tissue.

The technical procedure that we have employed most often for inoperable carcinoma of the antrum and pylorus is the method devised by von Eiselsberg.²⁰ This embodies a complete transverse severance of the

stomach above the limits of the tumor and entero-anastomosis of the jejunum and the proximal uninvolved segment of the stomach. The gastrocolic and gastro-hepatic ligaments are perforated close to the stomach proximal to the tumor. The gastric and gastro-epiploic vessels are doubly clamped, severed and ligated thereby freeing the lesser and greater curvatures of the stomach for a distance of from 3 to 4 cm. Two Payr clamps are then placed above the palpable limit of the tumor and the stomach is sectioned transversely either by cautery or by scalpel with sterilization by iodine. Although this incision should be well above the discernible margin of the carcinoma, it should not be so liberal as to permit the accumulation of secretion in this blind distal pouch. The mucosal and seromuscular layers are then closed by any of the conventional methods, thereby causing a complete division of the proximal and distal segments. After this closure was effected, von Eiselsberg anchored the distal stump to the proximal one to keep it in good position. We have never found this precaution to be necessary, since we cover the defect with omentum and have never seen the complication of herniation of the small intestine through the opening into the lesser omental sac.

The type of anastomosis selected depends on the local conditions within the abdomen and should be selected to afford the best functional result. The isoperistaltic posterior gastrojejunostomy is most commonly employed, although we have several times found the anterior method more readily done, in which case a lateral anastomosis is effected between the ascending and the descending limb of the jejunal loop. In other cases the posterior Polya or anterior Balfour end-to-side methods may be substituted.

This operation can be performed quickly and most efficiently with the use of the von Petz clamp. The application of this clamp across the stomach leaves two rows of closed silver clips, they are hemostatic and also give a watertight closure. A quick incision between the two rows of clips and continuous seromuscular sutures for the severed ends lessens the time consumed in this operation.

SUMMARY

The advantages of gastro-enterostomy for inoperable stenosing carcinomas are greatly enhanced by permanent exclusion of the involved pylorus, antrum and occasionally pars media, from the uninvolved proximal segment.

155 East Seventy-Second Street

The Sense of Continuity—In the continual remembrance of a glorious past, individuals and nations find their noblest inspiration and if today this inspiration so valuable for its own sake, so important in its association, is weakened, is it not because in the strong dominance of the individual, so characteristic of a democracy, we have lost the sense of continuity? As we read in Roman history of the scrupulous care with which even at such private festivals as the Ambarvalia, the dead were invoked and remembered we appreciate, though feebly the part which this sense of continuity played in the lives of their successors—an ennobling influence through which the cold routine of the present received a flow of energy from the touch divine of noble natures tone. In our modern lives no equivalent to this feeling exists, and the sweet and gracious sense of an ever-present immortality, recognized so keenly and so closely in the religion of Numa, has lost all value to us. We are even impatient of those who would recall the past, and who would insist upon the importance of its recognition impatient as we are of everything save the present with its prospects the future with its possibility.—Sir William Osler. Address delivered at Wistar Institute, 1894.

VALUE OF GORDON'S TEST IN DIAGNOSIS OF MEDIASTINAL HODGKIN'S DISEASE

REPORT OF TWO ILLUSTRATIVE CASES

ROBERTSON F OGILVIE M.D., M.R.C.P. (EDIN.)

Assistant in the Pathology Department of Edinburgh University,
Assistant Pathologist Royal Infirmary

AND

C. E. VAN ROOYEN, M.B. (EDIN.)

Halley Stewart Research Fellow, Bacteriology Department of Edinburgh University
EDINBURGH

Recently we¹ reported a case in which the clinical and postmortem naked-eye observations were not conclusive of Hodgkin's disease. The efficacy of Gordon's² test (1932-1933) as a means of diagnosing lymphadenoma was tried out with postmortem material obtained from this case. The test gave a positive result in favor of lymphadenoma and this was corroborated shortly after by microscopic examination of the tissues. The first case to be described here is similar but even more instructive, since it demonstrates the value of the new test as a diagnostic procedure in circumstances in which not only the clinical and naked-eye observations but even histologic examination of the tissues left an element of doubt in the diagnosis. This case is also interesting in that it illustrates the change in cell structure which the Hodgkin's lesion may undergo in the course of two or three years. Finally there is appended a note on a case of bronchial carcinoma together with the result of Gordon's test in that condition. This note is added, since bronchial carcinoma is a lesion that must sometimes be considered in the differential diagnosis of mediastinal Hodgkin's disease.

REPORT OF CASES

CASE 1 — Clinical History — A man, aged 59, a miner, admitted to the Royal Infirmary, Edinburgh, Nov. 15, 1933, under the care of Prof. Edwin Bramwell complained of weakness and loss of weight (with a duration of nine weeks), dyspnea and cough (six weeks), anorexia and sweating (three weeks). The patient was well until about nine weeks before admission, when one day he had an attack of shivering and went home to bed. He did not stay in bed and during the next three weeks he had repeated slight shivers sometimes two or three in a day. He felt himself getting weaker and people remarked that he was not looking well. Six weeks before admission he was compelled to take to bed because of weakness and about the same time he began to have a cough and to be short of breath. He never saw any blood in his sputum, which was yellowish, scanty and difficult to expectorate. The bowels were constipated and during this time he lost weight rapidly. His appetite was poor. During the three weeks prior to admission he sweated profusely when asleep and latterly his sleep had been disturbed.

Two years before he had a swelling removed from the left side of the neck. This swelling had been present for four years during which time it had enlarged slowly and latterly it had been red. About a year before admission he had noticed further swellings in the right side of the neck but he did not think these had grown much lately. They had never been painful or tender.

Previous illnesses included typhoid and rheumatic fever. There was no family history of tuberculosis but the patient lived in a small insanitary and overcrowded house. He used to take a fair amount of alcohol.

Physical Examination — The man looked ill, pale and emaciated but was cheerful and optimistic. There was considerable myotatic irritability. The skin was loose and atonic and the hair shabby and dry. The temperature was 101.4 F. The breathing was mainly abdominal and at the rate of 32 per minute. The chest was well formed but poorly clothed and moved equally on the two sides. There was no definite impairment of the percussion note, but a suggestive area of dullness was present over the middle zone of the right lung. The breath sounds on both sides were harsh and vesicular, with sibilant rhonchi toward the end of inspiration and some during expiration. Sputum was negative for the tubercle bacillus. A roentgenogram of the chest revealed a slight deviation of the heart and mediastinum to the right side, with infiltration of the medial part of the upper, middle and lower zones of the right lung, there was also thickening of the pleura in the lesser and greater fissures. The pulse was 136 per minute and regular in time and force. The blood pressure was 119 systolic 65 diastolic. The heart sounds were pure but feeble. The abdomen was rather prominent. On the skin of the abdomen and lower part of the chest there was a yellow scaly lesion, which had been present since the Boer War. There was no abdominal rigidity or tenderness. No abnormal swellings were present and there was no enlargement of the liver or spleen. Many enlarged glands were present in the neck and axillae. The Wassermann reaction was negative. There was nothing to note in the nervous system.

Clinical Diagnosis and Termination of Illness — In view of the clinical and radiologic evidence a diagnosis of pulmonary tuberculosis was made. The patient unfortunately went rapidly downhill and died six days after admission.

Postmortem Examination — **Macroscopic** The body was somewhat emaciated. The pericardial sac contained a small quantity of clear serous fluid. The left pleural sac contained half a pint of slightly blood-stained fluid, the right contained a few ounces of similar fluid. The peritoneal cavity was healthy. In the right bronchus just beyond the bifurcation of the trachea there was a new growth in the shape of firm, whitish slightly raised plaques. The growth extended down into the main branch of the right lower lobe and had actually spread for a short distance into the substance of this lobe. It extended upward into the trachea for 2 or 3 inches and also down the left bronchus and its larger branches. Both lungs were voluminous and emphysematous and showed marked carbon pigmentation. Numerous deposits of white tissue were scattered over the surfaces of both lungs. Patches of bronchopneumonia were present in the upper lobe of the right lung. The rest of the lung and also the left lung showed congestion and the bases of both lungs were edematous. Large masses of glands were found at the roots of the lungs. These extended up the trachea and communicated with similar large glands in the anterior triangles of the neck. Masses of glands were found in both axillae along the aorta and the common iliac vessels, at the porta hepatis and along the superior border of the pancreas. In all these situations the glands were discrete firm and elastic in consistency, and on section showed a whitish marbled surface. The heart was of globular, owing to dilatation of all chambers. The myocardium was very pale and soft. The coronary vessels and the aorta showed slight atheroma. The esophagus, stomach and intestine were free from pathologic change. The liver was of average size but pale. It was dotted throughout by small white deposits, the largest of which was a centimeter in diameter. The spleen was three times its normal size and nodular on the surface. On section it presented a dark red surface, throughout which were scattered nodules of white tissue. The pancreas showed nothing of interest. The genito-urinary system, beyond the abnormal pallor of the kidneys, was normal. A large deposit about 2.5 cm in diameter was found in the left parietal bone toward the vertex. It was similar in appearance and consistency to the glandular masses elsewhere. It involved the whole thickness of the skull but not the underlying dura. Other deposits were seen in several vertebrae (third fourth tenth and twelfth thoracic and first and second lumbar). The brain and its meninges were healthy, but the cerebral vessels were markedly atheromatous. The yellow marrow at the middle of the femur was replaced by whitish tissue.

² Gordon M. H. in *Order Thomas Rose Research on Lymphadenoma*. Baltimore: William Wood & Company, 1932. Gordon M. H. *Brit. M. J.* 1: 641 (April 15) 1933.

Microscopic Tracheal and pulmonary growths consisted of polyhedral cells with a moderate amount of clear cytoplasm and a nucleus varying in size and chromatin content. These cells were for the most part distributed indiscriminately, but occasionally, especially in the pulmonary growth, they tended to assume a palisade arrangement, though no actual acini were formed. In the tracheal growth, cells were occasionally seen that were larger than the others with a single lobulated nucleus or with from two to six nuclei irregularly arranged toward the center of the cell. No such cells were observed in the pulmonary growth. Special staining revealed the presence between the cells of a fine supporting reticulum. This malignant looking tissue was actively invading the mucosa of the trachea on the one hand and the alveoli of the lung on the other. Many mitotic figures were present throughout the tissue of both lesions.

In one of the lymph glands examined only a few small foci of lymphoid tissue were left. The remainder of the tissue presented appearances similar to those of the tracheal lesion though small giant cells with single lobulated or several nuclei were rather more numerous, and there was no palisade arrangement. Between the cells was a very definite fine reticulum. In another gland widespread necrosis had occurred with hemorrhage and the formation of hemosiderin.

In the liver small foci of new growth had developed in relation to some of the portal tracts. The microscopic appearance of these and also of the growths in the spleen, marrow, skull and vertebrae was similar to that of the trachea and lymph glands already described.

Biologic Test—A large gland removed from the left axilla was freed from superficial contamination by flaming with absolute alcohol, immersion in boiling water for two seconds and subsequent removal of loose surrounding tissue. The gland was then divided with a knife and a portion (about 1 Gm.) was removed from the center. This was finely divided and thereafter emulsified with pestle and mortar in 20 cc of broth of pH 7.1. The emulsion was divided into two parts, one of these was used for the immediate intracerebral inoculation of three rabbits, the other was allowed to stand for seven days in a refrigerator at $-4^{\circ}C$ and then was used for the inoculation of three additional rabbits. Inoculation consisted in the injection of 0.35 cc of the suspension into the occipital lobe of each animal to a depth of 3 mm. This was accompanied by the administration of an intravenous dose of 0.5 cc into the auricular marginal vein.

The three animals that were inoculated immediately with gland emulsion showed after four days signs of only slight ataxia, from which they rapidly recovered. The other three rabbits injected with emulsion which had been refrigerated for a week showed signs of gross nervous damage. These signs consisted of ataxia and incoordination setting in on the third day and progressing rapidly during the next few days to complete paralysis of the hind quarters with retraction of the head and nystagmus. On examination by aerobic and anaerobic methods of cultivation the brain and meninges of these animals yielded no growth. The test was therefore regarded as positive in favor of Hodgkin's disease.

COMMENT

The diagnosis of this case remained in doubt even after a naked-eye study of the organs and histologic examination of the various lesions. The main interest centers round the biologic test and the help it gave in determining the diagnosis.

The clinical diagnosis was pulmonary tuberculosis. Post mortem the diagnosis lay between (1) bronchial carcinoma and (2) Hodgkin's disease. The former was favored by (a) the age of the patient (59 years), (b) the presence of tracheal and bronchial lesions invading the right lung, (c) the presence in the pulmonary growth (right lung) of more or less columnar cells arranged in rows in the midst of an otherwise spheroidal-cell tissue, and (d) the indeterminate histology of the lesions in other organs. Points in favor of lymphadenoma were (a) a history of cervical glandular swellings for six years, (b) widespread lymphatic involvement (post mortem) and the character of the glandular masses, (c) involvement of the liver and spleen, (d) the presence in all the lesions of a fine but definite supporting reticulum, and (e) the occurrence in most lesions of cells like Hodgkin giant cells.

Although the weight of evidence was undoubtedly in favor of lymphadenoma, there yet remained an element of doubt. Consequently the result of Gordon's test was anticipated with interest and, as already indicated, it was positive. Since, moreover, bronchial carcinoma yields a negative biologic test (case 2) the lymphadenomatous character of this case seemed definitely established.

To complete the history, it should be stated that the gland which had been removed from the neck two years before death (1931) and examined elsewhere was later traced. It showed lymphoid hyperplasia with loss of gland architecture and in places proliferation of the endothelial cells among which were a few giant cells with a single lobulated nucleus or two or three nuclei. The condition was histologically one of early Hodgkin's disease. The case is thus also noteworthy as illustrating how the lymphadenomatous lesion, from being more or less characteristic, may in the course of time develop very atypical features and assume malignant characters.

CASE 2—Clinical History—A man, aged 61, a railway porter admitted to the Royal Infirmary, Edinburgh, under the care of Prof W T Ritchie, Oct 17, 1933, had had pain in the upper part of the left chest anteriorly for the past six months. For the past two months there had been a painful, tender swelling about 3.5 cm in diameter over the second left costal cartilage. Until a fortnight before admission he had been in good health except for the painful swelling, but since then he had felt weak and breathless on exertion and had noticed that his ankles were swollen, particularly in the evening. He had had a slight cough for years.

Physical Examination—The patient had an ashen complexion with a cyanotic tinge. Two firm tender lumps, each about 3 cm in diameter were present under the skin over the second left rib. The chest expansion was diminished. In the lower part of the right lung there were areas of low-pitched bronchial breathing with moist accompaniments, and in the left lung there was dullness with high-pitched bronchial breathing and whispering pectoriloquy. The cardiovascular, alimentary, genito-urinary and nervous systems showed nothing of interest. There was a slight degree of secondary anemia.

Postmortem Examination—The lungs were moderately emphysematous and showed some basal congestion. The right lung was otherwise healthy. In the left bronchus just beyond the bifurcation of the trachea there was a nodule of neoplastic tissue in the process of invading the adjacent lung substance. The nodule was continuous in the anterior mediastinum with a large, firm, creamy yellow new growth consisting apparently of enlarged lymphatic glands. The upper part of the left lung was collapsed and heavily infected, owing to bronchial obstruction. The mediastinal mass also extended through the intercostal spaces to form two nodules below the left pectoralis major. The right kidney contained a single large mass of tumor tissue similar to that described. The left lobe of the prostate gland had in it a nodule which superficially resembled the tumors elsewhere. The liver showed marked chronic venous congestion. The spleen exhibited no noteworthy abnormality. The abdominal lymphatic glands, with the exception of one on the right renal vein, showed no malignant involvement.

Microscopic examination of the thoracic mass proved it to consist of adenocarcinomatous tissue. Much of the tumor was very undifferentiated, but acini occurred here and there. The neoplasm had induced the formation of fairly abundant stroma. The lymph glands and right kidney showed invasion by similar tissue. A prostatic nodule was adenomatous in character and microscopically did not resemble the other neoplasms.

Macroscopic and microscopic observations together indicated a bronchial carcinoma

Biologic Test—Three rabbits were inoculated after the manner already described with tissue taken from the enlarged lymph glands—one immediately, October 19 (the day of the autopsy), a second on November 1, and a third on November 8. The material used to inoculate the last two rabbits was kept in a refrigerator at -4°C . All the animals remained normal, and the test was therefore regarded as negative.

SUMMARY

In case 1 the clinical and postmortem (macroscopic and microscopic) observations, while favoring Hodgkin's disease, did not conclusively support such a diagnosis. Gordon's biologic test was applied. The test gave a positive result, thus supporting a diagnosis of lymphadenoma. Case 2 is one which macroscopically resembled Hodgkin's disease. It yielded a negative biologic test and was ultimately proved by histologic examination to be a typical bronchial carcinoma.

These cases illustrate the value of Gordon's test as a diagnostic procedure in circumstances in which Hodgkin's disease is suspected.

DINITROPHENOL POISONING REPORT OF A CASE

HARRY JACKSON, M.D., AND ALBERT I. DUVALL, M.D. CHICAGO

History—J. M., a white woman, aged 42, married, a housewife, who weighed 70 Kg (154 pounds), was advised by her physician to take dinitrophenol, 0.1 Gm, three times a day. Thirty capsules of sodium dinitrophenol 2-4 (Eastman Kodak Company) were taken with a weight loss of 4 pounds (1.8 Kg) during ten days. There was no excessive sweating or other untoward symptoms, and with the telephonic consent of her physician the druggist supplied sixty more capsules. On the morning of the eleventh day, a slight rash, which itched moderately, appeared on the chest. On the night of the fourteenth day, a generalized erythematous papular eruption appeared over the whole body, including the scalp. These papules were hard and shotty, about 6 mm in diameter, and raised 3 mm. There was considerable discomfort from itching. The use of the drug was discontinued and the usual measures of diet and therapy were instituted to obtain relief. Sixteen ounces (475 cc) of magnesium citrate solution was immediately ordered, sodium bicarbonate baths, and alkaline mineral water in large quantities. Only sugar (candy), milk and water were taken in the diet, as the patient's appetite had disappeared. Calcium gluconate, small doses of mild mercurous chloride and atropine were ordered four times daily but had little effect, and the atropine was stopped after twenty-four hours. The itching became intolerable and the patient scratched her skin until blood appeared. She was restless, showed a marked trembling which was almost constant, and exhibited great anxiety. The temperature was raised and the pulse rapid. Ephedrine, three-eighths grain (0.024 Gm), and epinephrine hydrochloride, 10 minims (0.6 cc) by hypodermic injection relieved these symptoms for one to two hours. Later codeine, one-fourth grain (0.016 Gm), and amidopyrine, 5 grains (0.3 Gm), was given for pain.

On the fifteenth day, both hands and feet swelled to twice their normal thickness and the palms and soles were especially painful and itching. A wedding ring had to be clipped from the finger at 5 a. m. The papular eruption changed to large yellowish white wheals with reddish areas of skin between. The eyelids were swollen shut and the ears, neck and face distorted by swelling. The fingers could not be flexed, and it was impossible to grasp a water glass because of their stiffness. The patient was in great agony and had to be removed to a hospital for continuous nursing care. The trembling per-

sisted to a marked degree. The skin was hot and dry, although the patient felt chilly. She continued anxious and weak. The pulse range was between 120 and 140, the temperature, from 102°F to 103°F , the respiration rate, 24 to 30. The blood pressure was 128 systolic, 58 diastolic. The urine was scant (300 cc in twenty-four hours) despite forced fluids. The Derrien test for dinitrophenol was positive in the urine. Smell and taste had disappeared. There was marked pain in the region of the antral and frontal sinuses. There was yellowish discoloration of the sclerae, and the urine and blood serum were stained a deep yellow.

The pruritus and edema of the skin reached their height on the fourth day following the onset of the toxic symptoms, and during these four days the patient had slept but one hour at long intervals, usually following injections of pantopon, one-third grain (0.02 Gm), or morphine, one-fourth grain (0.016 Gm), given for pain and restlessness, and epinephrine and ephedrine for the pruritus. These were given as often as every four hours on the fourth day and less often on the other days. On the fifth day the eyes could be opened and the skin lesions were less pronounced, but these still recurred in waves. The mucous membranes now became affected, and there was intolerable vaginal pruritus, burning on micturition, and soreness of the mouth and esophagus. The lips suddenly began to burn and smart, and swelled greatly. These symptoms continued for thirty-six hours. On the sixth day there were isolated patches of urticaria on the dorsum of the hands and feet, about the joints and in the lumbar region. The sinus pain had disappeared and the urine was light, natural colored and abundant (2,000 cc). The patient fell into a sound sleep. Twice daily a gallon of sodium bicarbonate solution was used as a colonic irrigation, and hot boric packs were applied continuously to the region of the kidneys until there was abundant elimination. Daily cathartics were given. Local applications of calamine lotion, aluminum acetate solutions, and alkaline pastes had no effect on the pruritus. Olive oil rubs to soften the dense induration of the skin gave some relief. On the seventh day the Derrien test was negative in the urine. The temperature and pulse had returned to normal, and there was moderate pruritus, trembling and erythema, which was controlled by ephedrine. The skin was covered with scratch marks and showed desquamation. Appetite, taste and smell were normal and the patient was discharged from the hospital. There was a further loss of 4 pounds after the onset of the toxic symptoms, while the patient was on a sugar, milk and water diet.

Previous History—The patient had diphtheria at 8 years of age, for which antitoxin was administered. A tonsillectomy at 28 years required hemostatic serum for the control of hemorrhage. A marked urticaria followed this injection.

Laboratory Examination—Miss Isaacs of Highland Park Hospital made the following observations:

Fourth Day The urine was yellow and alkaline with a specific gravity of 1.023. It was positive for albumin, sugar and acetone and was negative for diacetic acid. Phosphates were present. The Derrien test was positive.

Fifth Day The urine was yellow and neutral, with a specific gravity of 1.007. Albumin was present and sugar was absent. Dinitrophenol was present by the Derrien test.

Sixth Day The urine was yellow and neutral with a specific gravity of 1.009. There was a trace of albumin. The reaction for dinitrophenol was negative.

Blood examination revealed hemoglobin, 102 (Sahl), leukocytes, 11,500, red blood cells, 4,090,000, polymorphonuclears, 84 per cent, polymorphonuclear eosinophils, 0, lymphocytes, 11 per cent, monocytes 2 per cent, 3 irritation cells.

Chemical examination revealed icterus index, 20, Van den Bergh, direct test negative, indirect test, faintly positive, sugar, 90, nonprotein nitrogen 27, uric acid, 3.5, Fouchet's test, negative. Three days later the icterus index was 5.3.

An electrocardiogram was negative.

COMMENT

There was a history of allergic reaction to horse serum only. As there was no history of chronic rheumatism, alcoholism, tuberculosis, renal disease or hepatic disease in this patient, or other forms of allergy, there were no contraindications to

its use as prescribed by Cutting, Mehrtens and Tainter¹ It might be asserted that the dose of 0.3 Gm daily was too large for a woman of 70 Kg, but this seems to be the dose generally prescribed in the cases I have since investigated in this vicinity

104 South Michigan Avenue

UMBILICAL ENDOMETRIOMA

ATTILIO GALASSO MD BYRON G SHERMAN MD, AND
VICTOR E BURN MD MORRISTOWN, N J

Attention was called by Babes as early as 1882 to the occurrence of ectopic endometrial tissue in a myoma uteri In 1883 and 1896 Diesterweg and von Recklinghausen, respectively, wrote on similar observations These reports were the first of a series by authors who found endometriosis (Sampson) to involve the female adnexa, peritoneum, broad ligaments, abdominal muscles, umbilicus and other viscera

The following is a brief review of the various theories concerning the origin of ectopic endometrial tissue

1 The wolffian theory Origin from the mesonephros was supported by von Recklinghausen This theory held sway until 1903 when Cullen demonstrated that the glandular inclusions in adenomyoma uteri were due to direct invasion of the uterine muscle from the mucosa

Fig 1—Compact stroma surrounding the gland on the left There is some mucin and cellular debris in the lumen

2 The muellerian theory This conception has been utilized to explain the presence of endometrial tissue in such locations as the umbilicus, inguinal region and rectovaginal septum on the basis of embryologic misplacement of muellerian tissue As yet, no satisfactory explanation of the mechanism involved has appeared in the literature

3 Serosal heterotopy Practically all German writers appear to support this theory on the ground that the peritoneum and the germinal epithelium of the ovary are capable of undergoing a metaplasia secondary to an inflammatory stimulus or, as Novak contends, secondary to an endocrine stimulus

4 Theory of implantation Many in America and England support Sampson's theory of endometrial regurgitation through the fallopian tubes at the time of menstruation There are others, however, who object to this theory on the ground that the viability of menstrual epithelium has never been proved This explanation is correct, would account for the presence of endometrial tissue in the umbilicus on the basis of lymphatic dissemination

Cases of endometrioma of the umbilicus are not frequently encountered Only thirty cases were reported up to 1926 and Spitz¹ succeeded in collecting the reports of only fifty-four cases up to 1932 Of the latter fifteen were reported in the

United States The *Quarterly Cumulative Index Medicus* notes the report of another in France in February 1933

This type of tumor occurs exclusively in women, usually during the fourth decade, although it has been found in a girl, aged 18 years The symptoms of pain and swelling referable to the mass, which at the time of the menstrual cycle may appear cyanotic, are most frequently complained of Vicarious

Fig 2—The same features are to be noted here as in figure 1

menstruation from sinuses has been reported in many cases Natural or artificial inhibition of the menses has relieved the symptoms permanently in many cases

REPORT OF CASE

Mrs L R, aged 36, white, admitted as a private patient of B G S, Jan 5, 1934, complained chiefly of pain and swelling and purple discoloration of the umbilicus since August 1933 The pain became more marked over a period of weeks and more so at the time of menstruation, when the umbilicus seemed to take on a darker purplish hue It never discharged The familial history and that of previous illness were negative Her periods started at the age of 14, occurring every twenty-eight days and lasting from five to six days, although, during the past four months, they persisted for eight or nine days There was no history of abdominal pain at the time of any

Fig 3—The type of epithelium is more clearly portrayed in this field

menstrual cycle The patient has a 9 year old child living and well and had one miscarriage at six and a half months

The physical examination was irrelevant except for the umbilicus, which appeared bluish measured 1 by 1 by 2 cm, was tender and nonfluctuating and seemed freely movable

At operation we excised the mass without opening the peritoneal cavity with which it did not communicate The wound healed by primary union

¹ Cutting W C Mehrtens H G and Tainter M I Actions and Uses of Dinitrophenol J A M A 101 193 (July 15) 1933

From the Morristown Memorial Hospital

¹ Spitz Herman Adenomyoma (Endometrioma) of Umbilicus Am J Clin Path 2 15, (Mar) 1932

On section the gross appearance of the cut surfaces was that of fibrous tissue containing several small cysts, from which a viscid brown fluid exuded. Microscopically there were seen many glands of varying size. Some of these glands were cystic in appearance and were lined by columnar or cuboidal epithelium. There was also evident a small quantity of mucin

Fig. 4—Cystic dilatation

and cellular debris in the lumens. The glands were surrounded by a cytogenic compact stroma, which resembled that of uterine mucosa. There was present in various parts of the section blood pigment, which occurred also in some of the phagocytes.

The pathologic diagnosis was umbilical endometrioma.

Therapeutics

THE THERAPY OF THE COOK COUNTY HOSPITAL

EDITED BY BERNARD FANTUS, M.D.
CHICAGO

NOTE.—This series of articles constitutes the therapy recommended by the chiefs of staff and their associates in the Cook County Hospital. In the preparation of these articles the copy is submitted to the various members of the staff by the director of therapeutics, Dr. Bernard Fantus. The views of the various members are summarized, after which a final draft is prepared for publication. Thus, in the article on insomnia which follows, fifteen physicians presented their views, and in others anywhere from five upward. The series of articles will be continued from time to time in these columns.—Ed

THERAPY OF INSOMNIA

Sleep is even more necessary for the maintenance of life than is food, for one cannot live as long without sleep as one can without food. Sleep is generally more important than medicine. Hence the patient's sleep should not be disturbed for medicinal treatment, unless continued effect is extremely important, when it should be definitely stated in the written order.

1 Comfort—The patient should be made comfortable as he understands comfort. The patient's sleeping habits as regards the number and size of pillows and the bed covering should be respected. A patient who has not slept well during the night and has just fallen asleep in the early morning hours should not be disturbed for the morning toilet. Better that the patient eat unwashed than die from exhaustion induced by insomnia.

2 Psychotherapy—As worry is one of the most potent causes of insomnia, the worry about insomnia constitutes a vicious circle that must be broken by whatever means may be required. The patient should understand that the time he sleeps seems short, that the time he lies awake seems long, and that a very few hours of sleep (possibly two) suffice to maintain life, the rest being more or less of a luxury. Reading and, better still, being read to, may take one's mind off worry and thus be sleep inducing. Suggestion plays an important part in the induction of sleep, and many an innocent and yet effective measure, such as "counting sheep" or focusing one's eyes at the tip of one's nose, depends on it. Suggestion, occasionally even in the "hypnotic" state, is the hypnotic to be used in hysteria, in which the medicinal hypnotics, even morphine, often fail. Reasoning and persuasion should be employed in neurasthenia as well as psychoanalysis which, even in its nontechnical sense, is often of value in sleep-preventing phobias, and mental hygiene as well as physical hygiene in any case of "nervousness" as, for example, elimination of excessive nerve tire produced maybe by a fifty mile ride to a suburban home or working at home after hours.

3 Physical Measures—The proper balance between rest and exercise holds the secret of sleep. Insufficient as well as excessive fatigue may make sleep impossible. Physical exertion may help one person's insomnia while aggravating that of another. In the latter case, rest treatment is indicated. Many a bed patient sleeps better for slow gentle massage or even a back rub at bedtime, sedative hydrotherapy, as a prolonged (one fourth to one-half hour) warm (96 F.) bath or cold wet pack of three quarters to one hour's duration, or even an abdominal or leg compress (a moistened stocking covered by a dry one). In cases of insanity the neutral bath for two or three hours or even applied continuously is a useful calmative measure, especially when combined with an ice cap. Appropriate antipyretic hydrotherapy is one of the best means of quieting the restless fever patient, the ice cap to lessen febrile delirium. A night cap should be used for the bald. Coldness of the feet may be antagonized by a hot foot bath, followed by brief cold affusions and a dry rub or by a hot water bottle to the feet (care being taken against burns). Warm blankets to the legs or woolen socks to the feet may suffice. The hypnotic value of the air bath deserves consideration, walking about in one's bedroom naked (except possibly for stockings and slippers) or even throwing off the covers while one is in bed and exposing the body to cool air for a short time may on subsequent covering, induce as the "reaction" the skin hyperemia requisite for sleep.

4 Diet—Avoiding large evening meals is especially important for those with poor digestion or circulatory debility, for whom the evening meal should be the lightest of the day. For those distressed by flatulence, the amount of starchy foods, fruits and vegetables should be reduced. Tea or coffee should be interdicted, especially at or near bedtime. On the other hand hunger may keep one awake, and a glass of hot milk with a cracker has hypnotic potency in such cases and might be a standing order against insomnia, unless of course the milk interferes with the fundamental dietary plan of treatment.

5 Relief of Distresses That Tend to Disturb Sleep—Rapid heart beat may be combated by a cold precordial compress or an ice bag wrapped in flannel,

dyspnea by elevation of the trunk to almost a sitting posture (see also dyspnea), cerebral congestion by cold to the head, heat to the feet, and magnesium sulphate (30 Gm) taken in concentrated solution during the day. To one distressed by a "heavy" meal, lemon juice may give relief. Flatulence may be antagonized by valerian (anionomiated tincture from one-half to

PRESCRIPTION 1—Sodium Bromide

R Sodium bromide	30 00 Gm
Water	30 00 cc
Syrup of glycyrrhiza	to make 120 00 cc

One teaspoonful in water (or milk) after meals and two teaspoonfuls at bedtime (Watch for bromoderma). If there is a tendency to rene the addition of solution of potassium arsenite (prescription 2) may lessen it (Price index 1 the approximate price per dose as compared with chloral 1)

PRESCRIPTION 2—Sodium Bromide and Solution of Potassium Arsenite

R Sodium bromide	30 00 Gm
Solution of potassium arsenite	10 00 cc
Water	30 00 cc
Syrup of raspberry	to make 120 00 cc

A teaspoonful or two in water (or milk) at bedtime (Watch for bromoderma) (Price index 1)

PRESCRIPTION 3—Valerian

R Elixir of ammonium valerate	60 00 cc
Elixir of sodium bromide	60 00 cc

From two to four teaspoonfuls in water at bedtime (Watch for bromoderma)

PRESCRIPTION 4—Carbromol

R 25 Carbromal tablets each	0 30 Gm
-----------------------------	---------

One or two at bedtime (May cause bromoderma) (Price index 20)

PRESCRIPTION 5—Barbital

R Barbital	2 50 Gm
------------	---------

Divide into ten capsules

Two with hot fluid two hours before bedtime and a third capsule may be given in two hours if required (Price index 5)

PRESCRIPTION 6—Phenobarbital

R 10 Phenobarbital tablets each	0 10 Gm
---------------------------------	---------

One or two one hour before bedtime (three should not be exceeded) (Price index 7)

PRESCRIPTION 7—Elixir of Phenobarbital

R Elixir of phenobarbital	60 00 cc
---------------------------	----------

From one teaspoonful to one tablespoonful at bedtime (each teaspoonful contains 0.03 Gm of phenobarbital)

1 teaspoonful) if gastric or by asafetida (0.3 Gm capsules) if intestinal, or a turpentine enema. Against nycturia, ingestion of fluid in the afternoon and evening should be restricted. For pain, analgesics should be prescribed, against cough, expectorants.

6 Sedatives—In conditions of exaggerated nervous irritability, bromide (prescription 1 or 2), though not a hypnotic, often favors sleep. It is perhaps best given at first in divided doses after meals and at bedtime and when improvement has set in, at bedtime only. Bromide should not be used in the insomnia of profound nutritional exhaustion of the brain or for those with acne. Valerian (prescription 3), especially when combined with bromide may be useful in insomnia accompanied by flatulence or palpitation, or when due to hysteria or dissimulation. Somewhat more powerful is carbromal (adalin, prescription 4), a sedative intermediate in potency between bromide and the true hypnotics. Acetylsalicylic acid and amidopyrine (either of them as a 0.3 Gm tablet) are sedative besides having analgesic, antipruritic and antipyretic value and they favor sleep, especially when given with bromide.

7 Hypnotics—These should be given only when other measures including sedatives have failed or probably will fail, and even then only temporarily to break in on the vicious circle of excessive fatigue-insomnia. In milder cases of insomnia partial sleeplessness is better than hypnotics with their frequently disagreeable after-effects and habit-producing tendency. They must nevertheless not be withheld when they are

actually needed. They may be life saving for a patient, fighting a serious disease such as pneumonia, who may succumb from lack of sleep, when the skilful use of hypnotics and letting him sleep as much as possible day or night may tide him over the crisis. Hypnotics are indispensable in conditions of great excitement, as in the psychoses and in febrile delirium. In these, 0.5 mg of scopolamine (hyoscine) hydrobromide hypodermically often acts best. At present barbital (veronal, prescription 5) in milder cases and phenobarbital (luminal, prescription 6 or 7) in more severe cases are the most popular. The barbiturates are useful when there is great restlessness in conditions of circulatory excitement, also in the presence of pain (especially when combined with coal tar analgesics). They are somewhat slow in acting, and hence had better be given one or two hours before the desired effect, and with hot fluid. As there may be sufficient residual sedative effect for one dose to favor sleep on the next night, it is good policy to order the hypnotic taken only if necessary on a night succeeding a sleepless night. In the presence of vomiting, phenobarbital sodium (prescription 8) may be given intramuscularly.

PRESCRIPTION 8—Phenobarbital Sodium

R Phenobarbital sodium	0 12 Gm ampule
------------------------	----------------

Dissolve in 1 cc of sterile distilled water and inject intramuscularly

PRESCRIPTION 9—Chloral Hydrate

R Chloral hydrate	15 00 Gm
Fluidextract of glycyrrhiza	30 00 cc
Syrup of orange	to make 60 00 cc

One teaspoonful in water (or milk) at bedtime. Repeat hourly—not more than twice—if patient is not asleep (Price index 1)

PRESCRIPTION 10—Chloral Hydrate Rectally for Children

Children's dosage of chloral hydrate given in starch water as retention enema

From 1 to 2 months	0 10 to 0 15 Gm
From 1 to 2 years	0 50 to 0 80 Gm
6 years	1 00 Gm
From 10 to 14 years	1 50 to 2 00 Gm

Contraindicated by cyanosis or impairment of circulation

PRESCRIPTION 11—Paraldehyde

R Paraldehyde	30 00 cc
Compound spirit of orange	30 00 cc

A teaspoonful or two in sweetened iced tea every hour until patient is asleep (Price index 3)

PRESCRIPTION 12—Paraldehyde for Rectal Administration

R Paraldehyde	30 00 cc
Alcohol	30 00 cc

Two teaspoonfuls in two tablespoonfuls of warm water as a retention enema

PRESCRIPTION 13—Sulphonethylmethane

R Sulphonethylmethane	5 00 Gm
-----------------------	---------

Divide into ten capsules. One or two with hot fluid at bedtime (when patient awakens too early) required. (By replacing each dose taken from the bottle with an equal amount of water the medicine may continue to have a satisfactory effect even though its strength becomes gradually less.) (Price index 8)

PRESCRIPTION 14—Codeine

R Codeine phosphate	0 50 Gm
Syrup of eucalyptol	60 00 cc

A teaspoonful or two in water at bedtime (Price index 12)

PRESCRIPTION 15—Morphine and Chloral

R Morphine sulphate	0 15 Gm
Chloral hydrate	15 00 Gm
Fluidextract of glycyrrhiza	30 00 cc
Syrup of orange	to make 60 00 cc

One teaspoonful in water at bedtime. Repeat once in an hour if required. (By replacing each dose taken from the bottle with an equal amount of water the medicine may continue to have a satisfactory effect even though its strength becomes gradually less.)

A differentiation must be made between sleep-inducing and sleep-maintaining hypnotics. Among the rapidly acting sleep-inducing hypnotics, especially indicated when the patient has difficulty in falling asleep, chloral hydrate (prescription 9) is the most potent. It is especially beneficial in sleeplessness accompanying high blood pressure. It must be used with caution.

when the circulation is enfeebled. It offers the greatest amount of hypnotic power per unit price. For children, its rectal administration (prescription 10) is the sovereign remedy, to be preferred to an opiate, even in the presence of pain, and to be shunned only in marasmus and if there is cyanosis. In cases in which chloral is prohibited, paraldehyde (prescription 11) acts rapidly and causes less depression to the circulation than any other hypnotic as powerful, but it has a most disagreeable odor, which it also imparts to the breath during elimination. In maniacal and delirious conditions it is best given by rectum in doses of from 4 to 8 cc mixed with an equal amount of olive oil or, when most rapid action is desired, with an equal volume of alcohol in 10 per cent aqueous solution (prescription 12). When the patient awakens too early, sulphonethylmethane (trional, prescription 13) may receive preference. The opiates are particularly valuable when pain or respiratory distresses interfere with sleep. Codeine (prescription 14) should be preferred whenever possible, but in severe conditions nothing does as well as morphine sulphate (from 0.010 to 0.015 Gm) hypodermically. Morphine should be avoided when there is pruritus or a tendency to urinary retention, and paraldehyde should be used. In obstinate insomnia, as that of delirium tremens, that resists these agents in safe doses given singly, results may be secured by combination of differently acting hypnotics, as morphine and chloral (prescription 15), which may, in a desperate case, be reinforced by scopolamine hydrobromide (0.5 mg) given hypodermically and by paraldehyde given by rectum. In the insomnia of psychoneurosis, euphorics, such as alcohol, opium, morphine, diacetylmorphine or cocaine, are strictly contraindicated. On the other hand, the hypnotics of the barbitol series (barbitol, phenobarbital) are often usefully prescribed even at the outset to break in on the vicious circle of neurosis-insomnia, in addition to appropriate psychotherapy and physical therapy. When the patient has had a fair number of nights of sound sleep, the medicine may be progressively reduced in strength to nothing, and this may be concealed from the patient until after the medicine has been discontinued, or, better, the patient's cooperation may be secured by having a dose of the drug within easy reach so that he might take it if required. The knowledge of having a positive remedy available will often give the patient the assurance necessary for repose, and he may not need the hypnotic. In any case, the use of hypnotics should not be continued for more than two or three weeks without endeavoring gradually to reduce the dose or to change the remedy. "Do not refill" should be written on every such prescription, and a supply for only a few days at a time should be ordered. The patient should be seen frequently enough during this period so that one can check up on the condition of sleeplessness, the existence of any toxic effects, or the advisability of decreasing or of increasing the dose or changing the drug.

8 Use of Stimulants—Such stimulants as caffeine or ephedrine, which ordinarily keep most persons awake, may relieve the insomnia of patients with hypertension, disturbed by cramps in the legs. Such agents are similarly valuable for patients unable to sleep by reason of Cheyne-Stokes breathing, which is generally made worse by the hypnotics mentioned. Strychnine also favors sleep in such cases, as well as in cases in which there is deficient aeration of the blood, as in emphysema with chronic bronchitis.

Council on Physical Therapy

THE COUNCIL ON PHYSICAL THERAPY HAS AUTHORIZED PUBLICATION OF THE FOLLOWING ARTICLE AND REPORT H. A. CARTER, Secretary

THE TEACHING OF PHYSICAL THERAPY TO UNDERGRADUATE MEDICAL STUDENTS

IRVING S. CUTTER, M.D.

AND

JOHN S. COULTER, M.D.
CHICAGO

No matter how vigorously the medical profession may deny utilitarian objectives in medicine, the physician, after all, to his patients in general is a healer, and his duty to the individual who is ill involves the use and application of all therapeutic measures conducive to the restoration of that patient to health. Many graduates are handicapped because of inadequate emphasis on therapeutic resourcefulness. Too often the clinical teacher gives the impression that, if a correct diagnosis is made, the treatment is easy. The patient desires to get well, hence, in the practice of medicine, therapy requires attention at least equal to that devoted to diagnosis.

There is, we believe, a growing consciousness on the part of the medical profession of the great value of the numerous procedures known as physical therapy. Realization of this has been aided by the establishment of the Council on Physical Therapy of the American Medical Association, and its publication of conservative articles on this subject, which have recently been collected in the Handbook of Physical Therapy.

Needless to say, physical therapy is probably one of the most misunderstood subjects in medicine. Its place in treatment is a matter of controversy, and, in the minds of many, the very mention of physical therapy recalls the picture of a room filled with a large assortment of brassy, shiny, complicated, electrical machines and lights. Certain physicians feel that some physical therapeutic procedures may be of value, but they mistrust them for their patients because of inability to advise the correct treatment. This is due, in some measure, to the high powered sales organizations of certain manufacturing concerns which have flooded the market with physical therapy equipment, and the conscientious physician, anxious to serve his patients, is too often driven to the purchase of equipment the use of which he does not understand, the application of which he knows but little about, and of the dangers of which he is unaware. It is essential, therefore, that students should know that it is not necessary to possess elaborate apparatus in order to apply physical therapy, the best physical agents to use are usually the cheapest, the simplest and the easiest obtained—heat, massage, exercise and water. These can be used by any physician in any place if he has had proper instruction in their application.

The present generation has witnessed an abrupt swing from polypharmacy to the use of a few drugs—that use based on sound physiologic principles. The coming generation will witness a swing away from the use of elaborate machines in physical therapy to the use of simple agents applied by physicians with a knowledge

of their physiologic action, the pharmacology of physical therapy

If the medical student can be taught to use simple physical agents, and, if he knows how to instruct his patient in their use in the home, substantial progress will have been made. The "chronic" is the bugbear of medical practice and but few physicians have devoted real study to the plight of this distressing group, the members of which furnish the irregular cultist with most of his patients.

The time must soon come when as intensive study will be directed toward the amelioration of chronic ailments as has been devoted to diabetes, pernicious anemia and thyrotoxicosis. With the development of a program of treatment for chronic cases, such as a group of patients with arthritis, home agents being used for prolonged periods, as much may be accomplished as could be accomplished by means of prolonged sanatorium management, if not more.

The value of physical therapy is evidenced in the reports of its use in all branches of medicine. A prominent surgeon recently stated, "I look to the more general and intelligent use of physical therapy, not by physical therapists but by physicians, as the means of making the next great advance in the treatment of fractures." A distinguished internist has recently stated that physical therapy must take its place at the head of the various forms of treatment directed toward arresting the progress of cardiovascular disease. He says

There are two main reasons why, in the treatment of cardiovascular disease, physical therapy has been practically ignored in this country

First, that from lack of training or interest or both, the average American physician knows little of the types of physical therapy that may help cardiovascular patients and still less concerning the effective, detailed manner of applying treatment. Lack of interest usually accompanies lack of knowledge concerning a given subject.

Second, that following the usual rule of supply and demand, since there has been no demand for thermal stations, spas or establishments in which physical therapy is properly given in this country, relatively few such establishments are available.

Lewinsky-Corwin says

The problem of chronic disease is an important social problem which the medical profession will some day be forced to realize and meet in an adequate manner. There is no doubt that the failure on the part of the medical profession at large to employ all the means at its disposal to deal with chronic disease has been responsible for the growth of cults. The relief which many patients receive from the administration of the various kinds of physical and psychic therapy practiced by the exponents of these cults has resulted in the development of spurious practices which often are as injurious to the individual and inimical to the public health as they are lucrative.

In a recent analysis of fifty hospitalized cases of chronic arthritis in the Mayo Clinic the following facts appear. Although the average duration of these cases was 57 years, only sixteen patients had been advised by their regular physician to have massage, only eight had been given exercises, corrective or preventive, and only four had been given supervised applications of heat for a period longer than two months. About half of this group had been sent to spas or other sanatoriums, which would indicate that the importance of physical therapy had been partially recognized.

The foregoing would seem to indicate that every medical graduate should have received some instruction

in physical therapy. At Northwestern University Medical School, in the eleven lectures allotted to physical therapy two are given to a review of physics of electrical and radiant energy.

The subject must then be approached not as a specialty but as a part of general medicine—not, as some one has said, by a fragment of an educator addressing himself to a fragment of a student on a fragment of a subject. Furthermore, physical therapy must be coordinated so that it will not be independent but correlated with the regular course in therapeutics.

To demonstrate the beneficial role of physical therapy, clinical dispensary and hospital physical therapy departments must be established. These departments should be reference departments. All cases would come from other clinical departments, the necessary laboratory and clinical examinations having been made. The patient would be accompanied by a request for treatment, to be prescribed by the referring physicians or the physicians of the physical therapy department, and executed by technicians who should be graduates of a school approved by the American Physiotherapy Association.

This department would be under the division of medicine with the director a member of that division and having the qualifications suitable for the rank of associate or assistant professor.

As the clinical departments of the medical school become familiar with the activities of the physical therapy department, the medical student will be taught physical therapy in all the clinical departments with the burden on the department of physical therapy proper to demonstrate the technique and detailed administration of physical agents.

It is also desirable to have a physicist in this department or have some direct connection with the department of physics. In the physical therapy department of Northwestern University Medical School we have a lecturer on applied physics, who gives two lectures on these subjects each year to the undergraduates. He also aids in the solution of research problems that are submitted to the physical therapy department by other clinical departments. In the last year some of these have been a method of measuring dosage of ultraviolet radiation in skin diseases, the method and amount of high frequency current to be used in an eye operation, the method for the use of high frequency currents in nose and throat cases, and an electrical cutting device for the genito-urinary department and for the neurologic division.

The dispensary clerks come in contact with these problems also and thus appreciate the value of a knowledge of the physics of these subjects.

After much experimenting at the Northwestern University Medical School, extending over six years, we believe that this subject can be taught only with a minimum of eleven lectures. This does not mean that a recommendation of this number of hours has been adopted as a requisite by the Council on Physical Therapy. This should be given to the junior class. The subjects of these lectures cannot be given in detail in this paper, but the Council on Physical Therapy will furnish a synopsis of these lectures on request. It is a required course for the whole junior class. The textbook is the Handbook of Physical Therapy, edited by the Council on Physical Therapy and published by the American Medical Association.

The object of these lectures is to impress the medical student with the use of simple agents of physical therapy and to prescribe these as he would drugs. In order to make this prescribing possible, we have directions mimeographed for the home use of heat, massage and exercises. The importance of a program of treatment is outlined, where instructions in the use of these physical agents are given to the patient and some member of his family. The medical student is also taught the physics of electricity and radiation. As these topics are each the subject also of a clinical lecture, the medical student will be enabled to judge the value of these machines and lamps himself and not have to take instruction from the manufacturers of such apparatus.

In the senior year, students in groups of two or four spend eight periods of two hours each in the physical therapy department of our dispensary. Here forty patients are treated daily. The medical students here actually observe the uses of these physical agents.

MODEL "C" KROMAYER LAMP ACCEPTABLE

The Hanovia Chemical and Manufacturing Company has submitted for the Council's consideration a recent addition to its line called the Model "C" Kromayer Lamp. The company claims that this lamp is designed especially for irradiation of various body cavities. Several sizes and shapes of burners are available (CR-2, CN-3, CS-4 and CU-5). The burners are of transparent fused quartz shaped in the form of applicators

Model C Kromayer Lamp with
Lowsley Wang Burner (CU-5)

closed at one end, and contain mercury and certain rare gases such as krypton, neon and xenon. At the other end they terminate in hard rubber holders $6\frac{1}{2}$ inches long and $1\frac{1}{4}$ inches in diameter. The electrodes and lead-in terminals are enclosed in the holders, and each burner and holder has its own flexible connector with terminal pins attached to the electrical control box. The box contains a step up transformer and regulating choke coil.

The light from the mercury glow completely fills the quartz tubes of the burners and, of course, the energy is emitted from the sides of the tube as well as the ends. The electrical characteristics are as follows:

110 volt 60-cycle alternating current				
Electrical current to controls				0.6 ampere
Maximum wattage				200 watts
Voltage delivered to burner				1500.0 volts
Maximum wattage in burner				100 watts
Erythema Time on Untanned	Skin (in seconds)			
Burner	CR 2	CN 3	CS 4 (Lowsley)	CU 5
First intensity	60	20	30 (Wang)	25
Second intensity	38	12	17	15

One unit was examined in a physical laboratory acceptable to the Council. The report reads:

"We have examined the spectral radiation from the tip of the Lowsley-Wang burner (CU-5) and have found that 94% of the total radiation of wavelengths shorter than, and including 3,130 Å, is concentrated in the wavelength at 2,537 Å. This is in agreement with the manufacturer's claims that 'about 90% of the therapeutic ultraviolet is concentrated in the wavelength at 2,537 Å'."

One unit was also investigated in a clinic acceptable to the Council. The clinical claims made for it by the Hanovia Chemical and Manufacturing Company were in agreement with the Council's findings. Furthermore, the advertising matter apparently conforms with the Official Rules of the Council. Therefore, the Model "C" Kromayer Lamp (including burners CR-2, CN-3, CS-4 and CU-5—Lowsley-Wang) is included in the Council's list of accepted devices.

Committee on Foods

THE COMMITTEE HAS AUTHORIZED PUBLICATION OF THE FOLLOWING
AMENDED GENERAL DECISION

RAYMOND HERTWIG.

VITAMIN CLAIMS IN FOOD ADVERTISING

Indefinite or general vitamin claims are vague, noninformative and misleading and do not permit a distinction between foods as sources of the respective vitamins. Vitamin claims shall stipulate the specific vitamin or vitamins present. Vitamins present in a food in insufficient quantity to contribute in any significant manner to the respective vitamin values of the diet do not warrant mention. It is desirable that warranted vitamin claims be expressed in appropriate terms indicative of the relative potency of the food as a source of the vitamins in the dietary schedule. Foods may be considered relatively as fair, good and excellent or rich sources of vitamins. State-ments of vitamin unitage in numerical quantities per gram (and per ounce if desired), where established, are to be encouraged on container labels and in advertising. The type of unit used should be specified. These statements shall be so expressed as not to be misleading.

Relative distribution of the vitamins in the various foods is presented in tables by Sherman (Chemistry of Food and Nutrition, fourth edition, 1932), by Rose (Foundations of Nutrition revised edition, 1933) and by a committee appointed jointly by the Lister Institute and the Medical Research Council of England (Vitamins: A Survey of Present Knowledge, 1932). These tables should serve as a guide for comparative vitamin claims for foods in advertising.

ACCEPTED FOODS

THE FOLLOWING PRODUCTS HAVE BEEN ACCEPTED BY THE COMMITTEE ON FOODS OF THE AMERICAN MEDICAL ASSOCIATION FOLLOWING ANY NECESSARY CORRECTIONS OF THE LABELS AND ADVERTISING TO CONFORM TO THE RULES AND REGULATIONS. THESE PRODUCTS ARE APPROVED FOR ADVERTISING IN THE PUBLICATIONS OF THE AMERICAN MEDICAL ASSOCIATION AND FOR GENERAL PROMULGATION TO THE PUBLIC. THEY WILL BE INCLUDED IN THE BOOK OF ACCEPTED FOODS TO BE PUBLISHED BY THE AMERICAN MEDICAL ASSOCIATION.

RAYMOND HERTWIG Secretary

JELKE GOOD LUCK THOUSAND ISLAND DRESSING

Manufacturer—John F. Jelke Company, Chicago

Description—Salad dressing containing cottonseed (or corn) oil, water, sweet pickle relish, sucrose, distilled vinegar, chili sauce, eggs, corn starch, salt, tapioca flour, mustard and paprika.

Manufacture—The ingredients in definite proportions are prepared and admixed as described for Jelke Good Luck Salad Dressing (THE JOURNAL, May 5, 1934, p. 1472).

Analysis (submitted by manufacturer) —

	per cent
Moisture	37.0
Total ash	5.3
Sodium chloride	4.6
Fat (ether extract)	42.5
Protein (N X 6.25)	1.1
Reducing sugar as invert sugar	5.1
Sucrose (copper reduction method)	4.3
Crude fiber	0.6
Carbohydrates other than crude fiber (by difference)	12.5
Titratable acidity as acetic acid	1.0
Lipoid phosphoric acid as P ₂ O ₅	0.047
Total phosphoric acid as P ₂ O ₅	0.043

Calories—4.4 per gram 125 per ounce

YEAST-RICH ARTAB

Manufacturer—Kitchen Art Foods, Inc., Chicago

Description—Mixture of cornstarch, dried yeast, sucrose, hydrogenated cottonseed oil, skim milk powder, glycerin oil of orange, and vanilla in tablet form.

Manufacture—The cane sugar, cornstarch, skim milk powder, yeast and vanilla in formula proportions are thoroughly mixed. The hydrogenated cottonseed oil, glycerin and oil of orange are

kneaded in, one half ounce portions of the dough are compressed into tablet form by means of punches and dies, the tablets are allowed to stand for twenty-four hours, wrapped in cellophane paper and packed in pasteboard boxes

Analysis (submitted by manufacturer) —

	per cent
Moisture	4.3
Ash	1.9
Fat (ether extract)	20.6
Protein (N X 6.25)	13.4
Reducing sugars as dextrose	9.8
Sucrose (copper reduction method)	12.8
Crude fiber	0.2
Carbohydrates other than crude fiber (by difference)	59.6

Calories—4.8 per gram 136 per ounce

Vitamins—By vitamin assay, the yeast ingredient contains at least 45 B units and 35 G units (Sherman) per gram

Claims of Manufacturer—One Artab block contains 3.25 Gm of dried yeast, equivalent in vitamins B and G to three moist yeast cakes, approximately 140 units of vitamin B and 110 units of vitamin G (Sherman)

SUPERB BRAND WHITE SYRUP

GOLDEN RULE BRAND WHITE SYRUP

Distributor—Tolerton & Warfield Co, Sioux City, Iowa

Packer—Penick and Ford Sales Company, Cedar Rapids, Iowa

Description—Table syrup, corn syrup base (85 per cent) with rock candy syrup (15 per cent), the same as Penick Syrup Crystal White (THE JOURNAL, April 9, 1932 p 1268) except that rock candy syrup is used in the packing of this brand instead of cane sugar syrup, as is used for packing Penick Syrup Crystal White

STOKELY'S FOR BABY SPECIALLY PREPARED STRAINED VEGETABLE SOUP

SEASONED WITH SALT

Manufacturer—Stokely Brothers & Company, Inc, Indianapolis

Description—Blend of sieved carrots, peas, spinach, celery, potatoes, lima beans and tomato juice with beef broth, rice and barley flours, slightly seasoned with salt, largely retains the natural minerals and vitamins

Manufacture—Good quality carrots and potatoes are washed, peeled, finely cut and sieved in a steam atmosphere through a screen with openings of a size to produce the desired fineness and texture. Medium size canned peas and small green canned lima beans are similarly sieved. Fresh spinach whenever available, is inspected, trimmed, washed, cut and sieved. If fresh spinach of high quality is not available, Stokely's Specially Prepared Strained Spinach is used. Celery stalks are cleaned and ground to medium fineness. The tomato juice is prepared to retain largely its natural vitamin content. The beef broth per pint contains approximately the meat extractives from a pound of lean beef and a portion of bone. The beef broth, vegetables barley and rice flours, and salt in definite proportions are thoroughly mixed, heated and filled into enamel lined cans, which are sealed and processed

Analysis (submitted by manufacturer) —

	per cent
Moisture	85.0
Total solids	15.0
Ash	1.4
Sodium chloride	0.8
Fat (ether extract)	0.1
Protein (N X 6.25)	3.0
Reducing sugars as dextrose	1.0
Sucrose (copper reduction method)	0.5
Crude fiber	0.4
Carbohydrates other than crude fiber (by difference)	10.0
Alkalinity of ash (cc normal acid per gram ash)	1.8
pu	5.7

Calories—0.5 per gram 14 per ounce

Vitamins—The natural vitamin content is retained in large measure in the manufacturing process by the use of equipment and procedure which exclude incorporation of air. The vegetable material is exposed to steam only.

Claims of Manufacturer—Supplementary to the infant milk diet, and valuable for children and adults on soft diets. Has smooth consistency and supplies desirable bulk without rough-

ness. The straining renders the nutrient content readily available for digestion. Scientifically prepared to retain in high degree the natural flavor, mineral and vitamin values. Seasoned to bring out full flavor and packed in enamel lined cans. Requires only warming for serving.

CAREY-IZED SALT IODIZED PIONEER SALT IODIZED

Manufacturer—The Carey Salt Company, Winnfield, La

Description—Table salt containing 1 per cent carbonate of magnesia and 0.02 per cent potassium iodide

Manufacture—Carey's Free Running Salt (THE JOURNAL, Aug 26, 1933, p 676) is admixed with 1 per cent magnesium carbonate and 0.02 per cent potassium iodide

Claims of Manufacturer—This iodized salt is for all table and cooking uses of salt. The magnesium carbonate tends to preserve its free running qualities. The iodine in the salt aids in preventing goiter caused by insufficient iodine in the diet. Used daily as the only salt on the table and in cooking, it richly supplements the iodine of diets deficient in that element. Does not cake or harden in the package.

FIVE-O CHOCOLATE FLAVORED DRINK BASE KRIM-KO CHOCOLATE FLAVORED DRINK BASE

Manufacturer—Krim-Ko Company, Chicago

Description—Drink base for preparing special beverages containing sucrose, water, chocolate and cocoa, tapioca flour, salt, agar, tartaric acid, flavored with imitation vanilla

Manufacture—The ingredients in definite proportions are heated together. The mixture is homogenized, cooled, packed in five gallon tin cans and distributed only to dairies and licensees for the preparation of special Krim-Ko beverages

Analysis (submitted by manufacturer) —

	per cent
Moisture	23.0
Ash	1.7
Fat (ether extract)	4.9
Protein (N X 6.25)	1.9
Reducing sugars as invert sugar	39.9
Sucrose (copper reduction method)	18.5
Crude fiber	0.5
Carbohydrates other than crude fiber (by difference)	68.0
Caffeine and theobromine	0.21

Calories—3.2 per gram 91 per ounce

Claims of Manufacturer—For preparation of special Krim-Ko beverages in accordance with specific license contracts and conditions of preparation

SILVER DRIP BRAND CRYSTAL WHITE SYRUP

Distributor—Union Sales Corporation, Columbus, Ind

Manufacturer—Union Starch & Refining Co, Granite City, Ill

Description—A table syrup, corn syrup sweetened with sucrose, flavored with vanilla extract

Manufacture—Same as Pennant Crystal White Syrup, THE JOURNAL, Jan 30, 1932, page 403, except that less sucrose is used

Analysis (submitted by manufacturer) —

	per cent
Moisture	24.5
Ash	0.3
Fat (ether extract)	0.0
Protein (N X 6.25)	0.05
Reducing sugars as dextrose	30.7
Sucrose (invertase method)	7.5
Dextrins (by difference)	36.9
Titratable acidity as HCl	0.01
Sulphur dioxide as SO ₂	0.001
pu	4.8

No methods are available for accurately determining the composition of syrups of this nature, therefore the foregoing analysis is roughly approximate

Calories—3.0 per gram 85 per ounce

Claims of Manufacturer—For table use and as a carbohydrate supplement for milk modification in infant feeding

THE ESTIMATION OF VITAMIN C

The importance of a supply of antiscorbutic substances in the diet was appreciated long before the development of knowledge concerning vitamins. Scurvy was recognized as a true deficiency disease, and the belief was fortified when it became possible to develop the malady experimentally in animals and to avert or cure it by suitable dietary supplements. In the "alphabet of vitamins" the unidentified antiscorbutic factor was designated as vitamin C. On the basis of experimental and empirical clinical observation great progress has been made in the elimination of scurvy through well established principles of preventive medicine. Almost every child is now supplied with antiscorbutic foods. Infantile scurvy has all but disappeared. Recently two incidents have added to the knowledge of vitamin C. Foremost is the discovery of the chemical nature of this organic food accessory. It is clearly recognized as one of the hexuronic acids, designated as ascorbic acid—a compound that can be prepared synthetically in the laboratory. The other contribution is the development of an indirect chemical method for the estimation of ascorbic acid in foods and tissues. This promises to enable investigators to dispense with the time-consuming biologic method of assay that has been in vogue for more than a decade.

For comparison in terms of a convenient unitage, citrus fruit juice has been used of late, in fact, the so-called international unit is based on such a standard. Now it seems destined to be supplanted by ascorbic acid itself as a standard. The product is already commercially available. According to comparative investigations by Harris and Ray¹ of the Nutritional Laboratory in Cambridge, England, 2 mg of ascorbic acid is equivalent in antiscorbutic potency to 3 cc of orange juice. This value agrees with the amount of ascorbic acid actually present in average specimens of orange juice or in "good" lemon juice, as determined by titration (from 0.6 to 0.7 mg per cubic centimeter). According to English assays, lemon juice is subject to

some variation in potency, so that the evaluation of ascorbic acid in terms of international units will depend on the quality of the lemon juice used for comparison, but taking the interpretation that the standard lemon juice means a "good" specimen showing from 0.6 to 0.7 mg of ascorbic acid per cubic centimeter on titration, ascorbic acid has a potency of 15 international units per milligram.

With the new methods of assay it has become possible to estimate the distribution of the indispensable ascorbic acid in the body. It is already known that the substance is quite widespread in various tissues and organs, in which the content is decreased whenever there is a shortage of vitamin C in the dietary intake. According to observations by Harris, Ray and Ward,² the amount of vitamin C excreted in the urine is surprisingly constant under ordinary circumstances, amounting to 30 or more mg a day. The British investigators state that if a normal individual is given a single large dose of vitamin C (for instance, 600 cc of orange juice, thirty times the reputed daily requirement), the concentration of vitamin C in the urine sharply rises, reaching in about three hours a maximum as high as, e. g., eight or ten times the "normal", it then rapidly drops again and within a day or so reaches the "normal" resting level of about 33 mg excreted daily, where it remains remarkably steady although the subject may be restricted for a week or more to a vitamin C-free diet. At present the minimum daily requirement is estimated at 1 ounce (30 cc.) of orange or lemon juice, or about 20 mg of ascorbic acid. It may become possible, by examination of the urine, to ascertain whether the supply of vitamin C falls below a safe margin, so that a diagnosis of latent avitaminosis can be made before other symptoms are apparent.

LEAD AND MULTIPLE SCLEROSIS

Perhaps the most striking manifestations of lead poisoning are those associated with an impaired nervous mechanism. Lead intoxication may be followed by a variety of neurologic symptoms, such as tremor, transient paralysis, convulsions, vertigo, temporary blindness, headache, insomnia, and mental lethargy or other disturbances. A recent report by Cone, Russel and Harwood¹ further incriminates this element as a neurotoxic substance by the suggestion that it may be an etiologic agent in multiple sclerosis of the exacerbating and remitting type. This conclusion was based on the finding of appreciable quantities of lead in the cerebrospinal fluid, brain, spinal cord and bones of a number of patients with this disease. In only a few instances did the case histories indicate the possibility of a previous exposure to undue amounts of lead, therefore there had undoubtedly occurred a slow chronic absorp-

tion of amounts too small to produce toxic symptoms. In several instances the appearance of the acute symptoms was preceded by some metabolic change caused by severe infections or by pregnancy and lactation. This was explained by the assumption that the lead which had been absorbed in earlier life had been stored, the subsequent metabolic changes caused its release in toxic amounts. That the foregoing explanation may be tenable is evident from a survey of reports in the literature describing the ubiquity of the distribution of lead, the ease with which it is absorbed, and the behavior of this element in the animal organism.

According to recent analyses,² many common foods, particularly fruits and vegetables which have been sprayed with insecticides containing lead, may contain small amounts of lead. Cognizance of this fact has resulted in the placing of a limit of 2 parts per million as the permissible maximum lead content of foods.³ Drinking water, cooking utensils, fumes, soot, dust particles and paint also may serve to introduce small quantities of lead into the body. Obviously, individuals engaged in occupations such as mining, plumbing and painting, which necessitate the constant handling or manipulation of material containing lead, may absorb additional amounts of this element. Thus it is evident that exposure to lead in varying quantities is inevitable under average modern living conditions. Lead may be absorbed readily from the respiratory and gastrointestinal tracts, and possibly also from the skin.⁴ After absorption it is apparently converted into a colloidal lead phosphate, transported as such in the general circulation to all parts of the body, and ultimately excreted or stored. Excretion may occur directly into the intestine or by way of the bile, the urine or possibly the skin. The amount of lead appearing in the excreta varies directly with the degree of exposure.² Mexicans living under "primitive" conditions and presumably subject to a minimal exposure excrete approximately 0.11 mg of lead daily in the feces and 0.014 mg per liter of urine whereas Americans, on the average, excrete approximately twice this amount. Individuals exposed to undue amounts of lead because of occupation may show an excretion from ten to twenty times greater than the average. The fact that appreciable quantities of lead appear in the urine of "normal" man shows conclusively that this element is absorbed into the blood stream and may come in contact with all body tissues. The available evidence indicates that lead may be retained temporarily by many tissues and that it may be deposited for prolonged periods in the bones. Ordinarily, lead stored in the bones remains inert but, as a result of certain stimuli, may be mobilized and appear in the circulation in a soluble form. The analogy between lead and calcium

in this respect is striking. Apparently the factors controlling the mobilization of calcium also influence that of lead. Indeed, it has been demonstrated recently⁵ that the production of an experimental acidosis in neurologic patients by the administration of ammonium chloride induces a decided increase in the amount of lead excreted in the urine and, in some instances, causes the appearance of detectable amounts in the cerebrospinal fluid. This can be most logically explained by assuming that a mobilization of stored lead has occurred. Thus there are indications that a slow, insidious accumulation of lead in the human organism may occur much more frequently than has been suspected and that the stored lead may serve as a potential etiologic agent in multiple sclerosis.

THE INTERPRETATION OF ERYTHROCYTE COUNTS

A recently published series of observations on the blood of healthy persons by Walters¹ at the University of Kansas offers some features for careful consideration by the physician who deals with blood examinations. The erythrocyte count, quantity of hemoglobin and volume of packed cells in eighty healthy men between the ages of 20 and 30 and determined after a half hour period of inactivity in the recumbent position were compared with those of eighty other subjects sampled after random uncontrolled activity. Resting subjects showed a significantly lower red cell count, hemoglobin and packed cell volume. Similar observations were made on twenty men, first after random activity and then one hour later after complete muscular inactivity in the recumbent position. Red cell count, total hemoglobin and total volume of packed cells showed a significant decrease following inactivity, while corpuscular volume, corpuscular hemoglobin and corpuscular hemoglobin concentration did not undergo any significant change.

It is not unusual for clinicians to make their diagnostic blood examinations while the patients are at complete rest. The possible influence of the enforced inactivity needs to be taken into account in the interpretation of the erythrocyte and hemoglobin observations. This is probably true also in relation to older persons of extremely sedentary habits, who are notably likely to exhibit low "blood counts" and thus present apparent aspects of mild anemia. There is nothing fundamentally new in the evidence that muscular activity, even for short periods of time, results in notable increases in circulating erythrocytes. The mechanism involved is fairly well understood. The spleen acts as a storage depot capable of increasing the oxygen-carrying capacity of the blood by the extrusion of considerable quantities of erythrocytes.

¹ Walters, O. S. The Erythrocyte Count, Quantity of Hemoglobin and Volume of Packed Cells in Normal Human Subjects During Muscular Inactivity. *Am. J. Physiol.* 105: 118 (April) 1934.

The lower figures after inactivity indicate an absolute decrease in circulating erythrocytes, owing to withdrawal of cells into storage. It has been alleged that the normal organism has a tendency to maintain the lowest degree of circulatory activity consistent with its requirements at any given time and will accordingly withdraw blood into storage areas whenever possible. Walters avers that the decreased red cell content in resting persons probably represents the converse of the erythrocytosis that occurs in exercise or emotion, both types of adjustment reflecting a delicate balance, which at all times appears to adapt the oxygen-carrying capacity of the circulating blood to the requirements of the tissues.

Current Comment

PHARMACOPEIAL VITAMIN
STANDARDIZATION

Elsewhere in this issue (Miscellany, page 1877) appears a comprehensive statement on standardization of vitamins issued by the Committee of Revision of the U. S. Pharmacopeia. The committee intends to issue interim revisions. The first of these has just been promulgated and deals with the methods and potencies of vitamin assay for cod liver oil. The new standards become official Jan. 1, 1935. It may be recalled that in the present Pharmacopeia there are two types of cod liver oil described: one that requires no assay and another that requires an assay of the vitamin A but not the vitamin D content. Even in the latter the vitamin A limits are low. For this reason the Council on Pharmacy and Chemistry has found it necessary to examine meticulously the protocols of assay of various accepted brands of cod liver oil. In each succeeding issue of *New and Nonofficial Remedies* it may be noted that the vitamin potencies of this or that accepted product have been increased as better methods of manufacturing technique have been developed. Also, supplies of cod liver oil have been found in which the vitamin activity is many times greater than that which was thought possible several years ago for an unfortified cod liver oil. In conformity with the progress for international standards, the new standards for the Pharmacopeia employ international units. These units are based on comparisons of the vitamin A and vitamin D activity of the oil to be assayed with a known reference oil. Using this method, the Committee of Revision has issued an order that all cod liver oil, labeled as such, which is sold in the United States shall have as minimum standards for vitamin A not less than 600 international units and for vitamin D not less than 85 international units per gram. This is approximately equal to 430 A. D. M. A. units or U. S. P. X units of vitamin A per gram or 32 Steenbock units of vitamin D per gram. It will thus be seen that cod liver oil in order to pass these minimum potencies must be of high grade. Some of the brands that have flooded the cheaper drug market must be considerably improved or they will cease to be marketed legally. Until the new U. S. P. standards are thoroughly established, however, those

who wish to avoid products of doubtful potency should confine their prescriptions to the brands that have been found acceptable by the Council on Pharmacy and Chemistry. Anticipating the action of the revision committee, the Council on Pharmacy and Chemistry at the last meeting issued a comprehensive statement on cod liver oil preparations which was published in the minutes. The Council requires that cod liver oils accepted for N. N. R. must have a vitamin potency of at least 850 vitamin A units per gram and 85 vitamin D units per gram when tested according to the revised method. It would serve physicians well to read the Council action in the light of the recent promulgation of cod liver oil standards.¹ The new U. S. P. standards do not cover products that have been fortified by the addition of viosterol or have been modified in such a way as to be sold as concentrates either in liquid or in tablet form. The average dose of cod liver oil as defined by the result of a cod liver oil questionnaire sent to pediatricians by the Council is three teaspoonfuls daily. The Council held at that time that the dosage contemplated the use of an oil having the potency of at least 400 U. S. P. units of vitamin A per gram, and at least 13.3 units (Steenbock) of vitamin D per gram. The pharmacopeial revision still recommends a dose of three teaspoonfuls daily for an infant. Calculated strictly under the new standards, one teaspoonful of cod liver oil gives approximately 310 vitamin D units and 2,200 vitamin A units (revised 1934 units), an increase in dose of vitamin A of approximately 40 per cent and vitamin D of approximately 240 per cent as compared with the hitherto accepted dosage. Physicians would do well to bear this in mind. The Committee on Revision and the Special Committee on Vitamin Standards are to be commended for their untiring efforts to place U. S. P. cod liver oil on a sounder basis.

THERAPEUTICS

With this issue *THE JOURNAL* begins a series of articles on therapeutics representing the methods of treatment used in the Cook County Hospital, Chicago, one of the largest medical institutions in the world. The responsibility for furnishing guidance to interns in large hospitals rests on the attending staff. Innumerable problems arise in the treatment of disease which demand the most careful consideration. It would no doubt be better if standing orders for routine methods could be eliminated entirely and every case considered wholly on its merits. However, in large institutions such orders are necessary because of the desirability of prompt action toward the relief of patients. The outlines of treatment that are included in the new series of articles on therapeutics represent the conclusions of conferences in which members of the staff representing various specialties have joined to give of their best thought and experience. An attempt has been made to limit the number of alternative procedures as much as possible. These outlines of treatment are not intended to be adopted in toto by other institutions but are merely suggestions based on successful results. Because

1. The minutes of the Council meeting appeared in *THE JOURNAL*, April 21, 1934, p. 1293. Reprints of this report will be sent to physicians on request.

of the number of men who contributed to the development of these outlines of therapy, it has been impossible to assign individual credit. It is understood that the outlines have been edited by the director of therapeutics in the hospital and that the entire staff bears a share of the responsibility for most of the procedures included.

Association News

THE CLEVELAND SESSION

Luncheon of the Phi Chi Fraternity

The Phi Chi Fraternity will hold a luncheon Thursday, June 14, at the Statler Hotel. The assembly will be addressed by Eben J. Carey, professor of anatomy and dean of the Marquette University Medical School, Milwaukee.

Banquet of Section on Gastro-Enterology and Proctology

The annual banquet of the Section on Gastro-Enterology and Proctology will be held at the Hotel Cleveland at 6:30 p. m., Wednesday, June 13.

Beware of Speed Traps

A physician who has evidently had some unpleasant experiences desires that those who drive their own cars to the Cleveland session be warned to keep under speed limits in all suburban areas around the city of Cleveland. Officers patrolling suburban roads do not ride on motorcycles but drive Ford cars and are said to be vigilant in arresting those who drive at a speed in excess of the ordinary limits.

MEDICAL BROADCASTS

National Broadcasting Company

The American Medical Association broadcasts on a coast-to-coast network each Monday afternoon from 3:45 to 4 o'clock. Central daylight saving time (3:45 Eastern standard time, 2:45 Central standard time, 1:45 Mountain standard time, and 12:45 Pacific standard time). The talk on June 11 from Cleveland will be broadcast at 6 o'clock Eastern daylight saving time. The next two broadcasts will be as follows:

June 4 Highway Hazards W. W. Bauer M.D.
June 11 The Common Cold Wilson G. Smilie M.D. (from Cleveland)

The National Broadcasting Company talks will be discontinued for the summer with the talk from Cleveland on June 11.

Columbia Broadcasting System

The Association broadcasts on a Western network of the Columbia Broadcasting System each Thursday afternoon on the Educational Forum from 4:30 to 4:45 Central daylight saving time. The June 14 broadcast will be from Cleveland from 4 to 4:15 p. m., Eastern daylight saving time. The next three broadcasts will be as follows:

June 7 The First Month W. W. Bauer M.D.
June 14 Medicine Marching Forward Morris Fishbein M.D. (from Cleveland)
June 21 Mischievous Misconceptions W. W. Bauer M.D.

Chinese Medicine—The story of medicine in China began in the hoary past. Her medical art certainly was well developed as early as 206 B. C. The founders were emperors and statesmen. The record is carried on from the standpoint of philosophers, with keen, logical reasoning, in which real intelligence and culture much labor and some truth are shown. Her ecclesiastics have definitely added a peculiar quota to the narrative, her pseudoscientists, in alchemy and astrology, have been most influential in contributing material, her magicians, exorcists, geomancers, necromancers, etc., have made the story turbid and unnatural, humbugs, coolies, quacks, scoundrels and deceivers have added a sinister note to the record—Morse, W. R. Chinese Medicine, New York, Paul B. Hoeber, Inc., 1934.

Medical News

(PHYSICIANS WILL CONFER A FAVOR BY SENDING FOR THIS DEPARTMENT ITEMS OF NEWS OF MORE OR LESS GENERAL INTEREST SUCH AS RELATE TO SOCIETY ACTIVITIES, NEW HOSPITALS, EDUCATION, PUBLIC HEALTH, ETC.)

CALIFORNIA

State Medical Election—Dr. Robert A. Peers, Colfax, was chosen president elect of the California Medical Association at its annual meeting, May 2, and Dr. Clarence G. Toland, Los Angeles, was installed as president. Dr. Emma W. Pope, San Francisco, was reelected secretary. The next annual meeting of the association will be held at Yosemite.

University News—The University of California, cooperating with the Metropolitan Life Insurance Company, began a practical training course for health officers, May 14, to continue twelve weeks. Participants in the course have access to well organized urban and rural health departments, where practical field observation and training are available and biometric and bacteriologic laboratory facilities are at hand.

Society News—The Hollywood Academy of Medicine was addressed by Dr. Sterling Bunnell, San Francisco, May 17, on "Reconstruction of the Hands." Papers were presented before the Los Angeles Surgical Society, May 11, among others, by Drs. Charles E. Phillips on "Myoma of the Stomach," and Rudolph Marx, "Effect of Hysterectomy on Endocrine Balance."—Dr. John D. Camp, Rochester, Minn., addressed the San Francisco County Medical Society, May 8, on "Roentgenologic Findings in Hyperparathyroidism."—At a joint meeting of the Solano County Medical Society and the Napa-Solano County Dental Association, May 8, in Vallejo, Dr. Anthony B. Diepenbrock and Bertram F. Coleman, DDS, San Francisco, discussed focal infection.

COLORADO

Society News—The Medical Society of the City and County of Denver was addressed May 15, by Drs. Henry W. Averill, Evans, on "The Common Cold," Charles A. Ringle, Greeley, "Otitis Media," and Charles B. Dyde, Greeley, "Quinotic Medicine."—Dr. William F. Spaulding, Greeley, presented a case report on hemolytic icteric anemia. The program was presented by the Weld County Medical Society.

Medicolegal Banquet—The physicians and lawyers of Denver held their annual banquet at the Denver Country Club, April 17, under the auspices of the Denver Bar Association. Dr. Walter W. King was toastmaster for the physicians and George C. Manly, dean emeritus, law school of the University of Denver, for the lawyers. Benjamin C. Hilliard Jr. spoke on "The Doctor in the Courtroom" and Dr. Arthur W. Stahl, "The Lawyer in the Hospital." Other speakers included Dr. John W. Ames, Dr. James R. Arneill, William Hutton and Edward King.

CONNECTICUT

Personal—Dr. Felix F. Tomaino has been appointed health officer of Danbury to succeed the late Dr. John J. Mayerick.—Dr. Theodore H. Sills has been appointed health officer of Newington.

Society News—Dr. Howard Fox, New York, addressed the Bridgeport Medical Society, April 3, on common skin diseases.—Dr. Graeme M. Hammond, New York, addressed the Stamford Medical Society, April 17, on "Suggestions in the Treatment of Epilepsy," and Dr. William P. Healy, New York, "Precancerous Lesions of the Vulva and Cervix."

GEORGIA

Society News—Speakers before the Fulton County Medical Society, May 3, included Drs. Rudolph A. Bartholomew and Emmett D. Colvin on "Advantages of Paraldehyde as a Basic Anesthetic Agent in Obstetrics." Dr. Kenneth R. Bell, Atlanta, presented a paper on "Cholecystography: Advantages of Intravenous Administration of the Dye" before the society, May 17.

ILLINOIS

State Medical Election—Dr. Charles S. Skaggs, East St. Louis, was installed as president of the Illinois State Medical Society at its annual meeting in Springfield, May 17. Dr. Charles B. Reed, Chicago, was chosen president-elect. Dr. Harold M. Camp, Monmouth, was reelected secretary.

Rockford has been designated as the place of the next annual meeting, and the date tentatively set for May 21-23

Society News—Speakers before the Adams County Medical Society in Quincy, May 14, were Dr Frank J. Jirka on health department activities, H. J. Shaughnessy, Ph.D., the doctor and the diagnostic laboratory, and Dr Robert H. Woodruff, mortality trends and vital statistics.—The Winnebago County Medical Society conducted its fourth annual clinical program at St. Anthony's Hospital, Rockford, May 2, with the following participants, among others: Drs. David S. Hillis, Chicago, "Problems of Pregnancy", Theodor Lang, Rockford, pathologic demonstration, Robert A. Black, pediatrics, Max S. Wien, Chicago, clinic on dermatology, Henry W. Meyerding, Rochester, Minn., orthopedic demonstration, and Aaron Arkin, Chicago, illustrated demonstration of lesions of gastro-intestinal tract

Chicago

Society News—Speakers before the Chicago Society of Internal Medicine, May 28, included Drs. William C. Buchbinder on "Relief of Thyrotoxicosis by Thyroidectomy", Willis Stanley Gibson and Edward J. Denenholz, "Rheumatic Heart Disease in Children", Louis Leiter, "Hypertension and Nephritis", Richard H. Jaffe, "The Neutropenic State", and James A. Connor, "Amebiasis".—At the annual meeting of the Chicago Tuberculosis Society, May 10, Dr. Ellis B. Freilich was elected president, Dr. Ralph B. Bettman, vice president, and Dr. Richard M. Davison, secretary.—The Cook County Physicians Association was addressed, May 25, by Drs. Samuel J. Fogelson and Hugo O. Deuss on medical economics

INDIANA

Society News—Dr. Ralph W. Elston, Fort Wayne, spoke before the Whitley County Medical Society in Columbia, May 8, on treatment of fractures.—At a meeting of the Knox County Medical Society in Vincennes, May 8, Dr. Clark E. Stewart, Vincennes, discussed "Insulin in Malnutrition".—The Jefferson County Medical Society was addressed, April 24, in Madison, by Dr. Lester A. Smith, Indianapolis, on "X-Ray Diagnosis of Childhood Tuberculosis".—The Elkhart County Medical Association heard Dr. Matthew Winters, Indianapolis, discuss "Summer Diarrhea and Gastro-Intestinal Upsets" at its meeting in Goshen, May 10.—Dr. Frank M. Gastineau, Indianapolis, addressed the Carroll County Medical Society in Camden, May 11, on "Common Skin Diseases in Adult Life".—At a meeting of the Randolph County Medical Society in Winchester, May 14, Dr. Alois B. Graham, Indianapolis, spoke on "Office Treatment of Anorectal Diseases".—The Gibson County Medical Society was addressed in Princeton, May 14, by Dr. Robert H. Crawford, Indianapolis, on "Pernicious Anemia and Its Treatment".—Dr. William R. Cubbins, Chicago, discussed "Injuries Around the Knee Joint" before the La Porte County Medical Society in La Porte, May 17.—At the one hundred and thirty-second semiannual meeting of the Union District Medical Association in Oxford, April 26, the speakers included Dr. Goethe Link, Indianapolis, on "Mild Chronic Thyroid Disease", Dr. Elmore B. Tauber, Cincinnati, "Commoner Skin Diseases", Dr. Vieri C. Griffis, Richmond, "Treatment of Harelip and Cleft Palate", and Albert Stump, attorney for the state medical association.—Drs. Karl R. Ruddell and Norman S. Loomis, among others, addressed the Indianapolis Medical Society, May 15, on "Tuberculosis of Abdominal Viscera"

IOWA

Society News—Dr. Erwin von Graff, Iowa City, spoke on ectopic pregnancy before the Washington County Medical Society in Washington, April 3.—Members of the Pottawattamie County Medical Society, all of Council Bluffs, presented the program before the Woodbury County Medical Society in Sioux City, April 19, speakers were Drs. Arnold L. Jensen on the traumatic abdomen, Gerald V. Caughlan, transurethral prostatic resection, and Raymond M. Rice, the education of the diabetic patient

Alumni Reunion—Announcement is made of a reunion, June 18, of the graduates of medicine, dentistry, pharmacy and nursing of the old college of Physicians and Surgeons of Keokuk Medical College and the combined institutions, which was in 1908 consolidated with Drake University and later with the University of Iowa. This will be the fourth reunion to be held in Keokuk, the first being in 1927, the second in 1928 and the third in 1930 which was attended by 20 per cent of the living graduates. Dr. William Rankin is chairman of the committee

KANSAS

Changes in Health Officers—Dr. Tarlton A. Hood, Garnett, has been named health officer of Anderson County, succeeding Dr. John N. Carter, Jr., Dr. Darrel L. Evans, Manhattan, has been appointed health officer of Riley County, to succeed Dr. John R. Mathews, resigned. Dr. Mathews will engage in private practice in Glenwood Springs, Colo. Dr. Fred E. Harvey is now health officer of Ottawa County, succeeding the late Dr. Joseph F. Brewer

MAINE

Obstetric Meeting—The spring session of the New England Obstetrical and Gynecological Society convened in Portland, May 16, under the presidency of Dr. Alonzo K. Paine, Boston. In addition to operative clinics, Dr. Harold J. Everett conducted a prenatal clinic, and Dr. Theodore C. Bramhall one on trichomonas vaginalis. The following physicians presented papers:

Thomas A. Foster and Carl M. Robinson Congenital Pyloric Stenosis
Walter F. W. Hay Extra Uterine Pregnancy
Clinton N. Peters and Langdon T. Thaxter, Pyelonephritis in Pregnancy
William Holt Results of Radium Therapy in 170 Cases of Uterine Carcinoma

Sir Duncan Campbell, journalist and traveler, Glasgow, Scotland, addressed the dinner meeting in the evening

MARYLAND

Review Course for Physicians—The division of medical extension of the University of Maryland will conduct a combined review course for physicians, June 4-22. Morning lectures will deal with advances in diagnosis and treatment in subjects chiefly from the field of general medicine and surgery, with a few lectures devoted to the specialties. The afternoons will be given over to the laboratory methods. The class will be divided into groups for ward rounds, and a clinic will be held daily. A matriculation fee of \$25 will be charged all registrants of Maryland, while the charge to persons coming from other states will be \$50. The course will be limited to twenty men. Further information may be had from the dean of the medical school, University of Maryland, Baltimore

Personal—Dr. Joseph LeRoy Wright, Jessups, for the last three years physician in charge of the Maryland House of Correction, has been named warden to succeed the late Joseph A. Delaney. Dr. Henry S. Shelley, Baltimore, has been appointed to succeed Dr. Wright.—Dr. Humphrey Warren Buckler, until recently acting assistant health commissioner of Baltimore, has been appointed full time medical health officer for the city health department. Dr. William K. Skilling has been named director of the bureau of child welfare.—Dr. Kenneth B. Jones, superintendent of the District Training School (federal), Laurel, and a former superintendent of the University Hospital, has been named to succeed the late Dr. Frank W. Keating as head of the Rosewood State Training School Owings Mills. Dr. Keating has been superintendent of the institution for thirty-seven years.—Dr. Johannes Frandsen, director of the National Health Service of Denmark, recently spent several days in Baltimore, accompanied by Dr. Poul R. T. G. Guildad, orthopedic surgeon with the health service. Dr. Frandsen is touring the United States as guest of the Rockefeller Foundation

MASSACHUSETTS

State Medical Meeting—The one hundred and fifty-third annual meeting of the Massachusetts Medical Society will be held in Worcester, June 4-6, in the Hotel Bancroft and Chamber of Commerce Building, under the presidency of Dr. William H. Robey. The Shattuck Lecture will be given, Monday evening, by Dr. Warfield T. Longcope, professor of medicine, Johns Hopkins University School of Medicine, Baltimore, on "The Importance of Disturbances in Nutrition in Edematous States". Dr. Lincoln Davis, Boston, president of the Boston Medical Library, will deliver the annual discourse, Wednesday afternoon, on "The Objectives of Medical Progress". Out-of-state speakers on the program include the following physicians:

Harold D. Corbuser Plainfield N. J. Conduct of the Convalescent Stage of Anterior Polymyositis
Ross Golden New York Diverticulosis, Diverticulitis and Carcinoma of the Colon. A Roentgenologic Discussion
Hermion C. Bumpus Jr. New York Transurethral Resection of the Prostate
Clay Ray Murray New York Management of Fractures About the Ankle Joint
Homer F. Swift New York Chronicity of Rheumatic Fever
P. Brooke Bland Philadelphia Intracranial Hemorrhage in the New Born from the Standpoint of the General Practitioner

A symposium on measurement of activity in pulmonary tuberculosis will be held, Wednesday morning, by Drs. Harry S. Wagner, Pocasset, Frank H. Hunt, Mattapan, Olin S. Pettungill, Middleton, Theodore L. Badger, Boston, Jacob Kaminsky, Waltham, Gullis L. Muller, Boston, John W. Cass Jr., Boston, and William H. Ordway, Mount McGregor, N. Y. Other physicians included on the program will be

Warren E. Wheeler, Boston, The Use of the Ketogenic Diet in Pyuria
Clement A. Smith, Boston, Present Status of Vaccination Against Tuberculosis
Sidney Farber, Boston, Role of the Streptococcus in So Called Sudden Death in Infancy and Childhood
Abraham Myerson, Boston, Social Conditioning of the Visceral Activities
Henry D. Chadwick, state health commissioner, Boston, Tuberculosis As It Affects the Physician's Practice

MICHIGAN

Hygiene and Public Health—The University of Michigan announces courses in hygiene and public health to be conducted, June 25-August 3, under the direction of Dr. John Sundwall, director of the division of hygiene and public health. The courses have been designed for health officers, public health nurses, sanitary inspectors, public health laboratorians, medico-social workers, psychiatric social workers, social workers and teachers and supervisors of school health education.

Social Service Survey—Dr. Haven Emerson and Dr. Gertrude Sturges, New York, are conducting a social service survey in Detroit, under the auspices of the Council of Social Agencies and the American Public Health Association. In addition, the Wayne County Medical Society is sponsoring a similar study. Combined questionnaires for the two surveys have been issued to every member of the society, containing fifteen questions on outpatient departments and social service work. A second questionnaire was sent to the chiefs of every hospital staff, with a copy to the superintendent, regarding outpatient service with special reference to the type and amount of dispensary service available in the community. The results of the questionnaires of the county society will be tabulated and submitted to the Council of Social Agencies to aid it in this study.

MINNESOTA

Basic Science Law Violated—Stanley C. Flanning recently pleaded guilty to practicing healing without a basic science certificate at Rochester and received a suspended sentence of five months in the Olmsted County Jail, according to the state board of medical examiners. He was placed on probation on condition that he refrain from practicing in the future. Formerly in the real estate business and with no medical training, Flanning had been treating at least two patients for diabetes in his room at a Rochester hotel, the treatment consisting of injections of insulin with a hypodermic needle. He stated to the court that he had treated only these two patients and that he had been in the "business" less than three weeks.

Hospital Meeting—The eleventh annual conference of the Minnesota Hospital Association was held at the Kahler Hotel, Rochester, May 24-25. In addition to the papers dealing with nursing, group purchasing and payment of hospital care, the following speakers, among others, participated:

Dr. William A. O'Brien, Minneapolis, Necessity of Greater Cooperation Between the Medical Profession, Hospitals and Other Allied Professions
Dr. Russell M. Walder, Rochester, Use of Special Purpose Foods in the Hospital
Dr. Walter C. Alvarez, Rochester, Foods 500 People Could Not Eat
Richard E. Scammon, D.Sc., Minneapolis, Hospital Libraries
Dr. Halbert L. Dunn, Minneapolis, The Minnesota Hospital Statistical Bureau

MISSISSIPPI

Society News—Dr. William P. Robert, Vicksburg, addressed the Central Medical Society, April 3, on infantile eczema, and Dr. DeWitt T. Brock, Jackson, acute conditions in the abdomen.—Dr. Charles M. Hammond, Walls, discussed the aid of the respirator in diseases of the chest before the DeSoto County Medical Society, April 2.—Dr. Ray M. Balvat, Oklahoma City, addressed a joint meeting of the Clarkdale and Six Counties Medical Society and the Delta Medical Society in Cleveland, April 11, among others, on diagnosis and treatment of allergic diseases.—The Harrison-Stone-Hancock Counties Medical Society was addressed in Biloxi, April 4, among others, by Dr. Edwin B. VanNess, Gulfport, on roentgen therapy.—A symposium on appendicitis constituted the program of the Issaquena-Sharkey-Warrar Counties Medical Society in Vicksburg, April 10.

MISSOURI

Illegal Practitioner Fined—William J. Voss was sentenced to one year in the work house and to pay a fine of \$100, April 3, for practicing medicine without a license. The maximum penalty for this offense was imposed by Judge Butler in the court of criminal correction in St. Louis. Voss is alleged to have treated numerous persons for "eye trouble." Although he was formerly listed in the telephone directory with the classification "Dr." and was known as "Dr. Voss" at the address where he was arrested, Voss admitted that he was not a physician. He was paroled from the Colorado State Penitentiary in 1918, after having served a sentence on a charge of issuing a bogus check. A warrant was issued against him the day of his trial in St. Louis, charging him with a similar offense.

NEBRASKA

Society News—Dr. Waltman Walters, Rochester, Minn., addressed the Otoe County Medical Society, Nebraska City, May 14, on "Lesions of the Stomach and Duodenum and Their Surgical Treatment."—Drs. George W. Covey and J. Marshall Neely, Lincoln, addressed the Omaha-Douglas County Medical Society, May 29, on Erythroblastosis with Erythroblastic Tumors in the Thorax, and "Abdominal Hodgkin's Disease," respectively.

NEW HAMPSHIRE

State Medical Election—Dr. Frederic P. Lord, Hanover, was chosen president of the New Hampshire Medical Society at its annual meeting in Manchester, May 16. Dr. Clifton S. Abbott, Laconia, was named vice president and Dr. Carleton R. Metcalf, Concord, reelected secretary. The next annual session will be held in Manchester, May 14-15, 1935.

NEW YORK

Public Meeting on Cancer—The New York City Cancer Committee sponsored a public meeting on cancer at the Hall of the Bar Association, April 26. Mr. Charles C. Burlingham, president of the Welfare Council, presided and the following speakers participated: Drs. John L. Rice, Alfred E. Shipley, John C. A. Gerster, James Ewing and Francis Carter Wood, Mr. William Hodson, commissioner of public welfare, and Clarence C. Little, Sc.D., director, American Society for Control of Cancer.

Personal—Dr. Lawrason Brown, Saranac Lake, was recently appointed a member of the state board of social welfare.—Dr. Rosella C. Wilder, Buffalo, has completed fifty years in the practice of medicine, having graduated from the University of Michigan Medical School in 1884.—Dr. Wallace J. French, Pike, was the guest of honor at a luncheon given by the Wyoming County Medical Society, April 10, at Perry, in celebration of his fiftieth anniversary in the practice of medicine. A radio was presented to him.

New York City

Eighth Harvey Lecture—The eighth lecture of the Harvey Society was delivered by Detlev W. Bronk, Ph.D., Johnson professor of biophysics, University of Pennsylvania, Philadelphia, at the New York Academy of Medicine, May 17, on "The Nervous Mechanism of Circulatory Control."

County Society Library—Greater use of the library of the Medical Society of the County of Kings during 1933 was recorded in the annual report of the librarian. During the year 13,079 readers consulted 55,333 books in the library and 10,147 books were taken out for home use, all these figures being increases over the corresponding figures for 1932. This library receives 1,518 serial publications and has on its shelves 131,858 volumes.

Bridge to Displace Hospital—A new bridge in process of construction has forced evacuation of eight buildings of the New York City Children's Hospital on Randall's Island because the land on which they stand is needed for the bridge right of way, the New York Times reported recently. Eventually all buildings will be removed from the island for the development of a city park, but some will be left for the present, it was said. Dr. Sigismund S. Goldwater, hospital commissioner, reported that he hoped to transfer some of the 400 children to state institutions.

Seventh Graduate Fortnight—The seventh annual Graduate Fortnight of the New York Academy of Medicine will be held October 22-November 2 and will be devoted to consideration of gastro-intestinal diseases. Sixteen hospitals will present coordinated afternoon clinics and clinical demonstra-

tions At evening meetings, clinicians from various parts of the country will discuss various aspects of the subject. A comprehensive exhibit of anatomic, bacteriologic and pathologic specimens and research material will be shown. A complete program and registration blank may be obtained by addressing Dr. Frederick P. Reynolds, New York Academy of Medicine, 2 East One Hundred and Third Street, New York.

University News—A student recreation center has recently been completed at Long Island College of Medicine, with a \$25,000 gift to the college from the Misses Jennie A. and Cornelia Donnellon. The donors' former residence, which adjoins the college, was bought and utilized for this purpose, according to their wishes.—Dr. Julius M. Rogoff, associate professor of experimental medicine, Western Reserve University School of Medicine, Cleveland, delivered the third of a series of lectures sponsored by the department of biology of New York University at the New York Academy of Medicine, April 11, on "Studies on the Suprarenal Cortex." The fourth lecture was delivered by Dr. Friedrich Gudernatsch, visiting professor of biology at the university, on "Thyroid Actions as Exerted by Thyrogenic and Thyrotropic Substances."—Dr. Max Thorek, Chicago, made an address at Columbia University College of Physicians and Surgeons, April 7, on "A New Method of Obliterating the Gallbladder by Electrosurgical Means."—Dr. Walter T. Dannreuther, among others, gave an address at the alumni day observance of the Association of the Alumni of Long Island College of Medicine, April 28, on "Postgraduate Education in Obstetrics and Gynecology."

NORTH CAROLINA

Society News—Dr. Alfred R. Shands Jr., Durham, addressed the Rutherford County Medical Society, Forest City, April 20, on "Bone Formation and Management of Fractures."—Dr. George E. Brown, Rochester, Minn., addressed the Buncombe County Medical Society, Asheville, in March on essential hypertension.—Dr. Robert W. McKay, Charlotte, discussed pyelitis before the Guilford County Medical Society, High Point, April 5.—Dr. Rufus P. Sykes, Asheville, addressed the Randolph County Medical Society, Asheville, in March, on jaundice.—A symposium on fractures was presented before the Catawba Valley Medical Society in Morganton, May 8, by Drs. Edward W. Pluifer, Morganton, Abner M. Cornwell, and John R. Gamble, both of Lincolnton.

OREGON

Society News—Speakers at a meeting of the Central Willamette Medical Society, Eugene, April 5, were Drs. Ralph A. Fenton, Portland, on "Research on Sinus Disease," Charles T. Swecney, Medford, "Carcinoma of the Large Intestine and Its Treatment," and Irvin R. Fox, Eugene, a case of Malta fever treated by vaccine.

Anniversary Celebration—The Multnomah County Medical Society observed the fiftieth anniversary of its founding with a banquet at the Portland Hotel, Portland, May 16. The society was established June 10, 1884. Olof Larsell, Ph.D., opened the program with a history of the society. Other speakers and the titles of their papers were Drs. Andrew C. Smith, "Fifty Years of Medical Progress," Banner R. Brooke and committee, "The Old Timers," and Ralph A. Fenton "Medical Preparedness in Oregon." Dr. Alfred Kinney, the first and fiftieth president of the Oregon State Medical Society, was also present and Dr. Adalbert G. Bettman acted as toastmaster. Of the twenty-four charter members of the Multnomah society, only three survive, Drs. Simeon E. Josephi, Cortez H. Wheeler, Portland, and Arthur Dean Bevan, Chicago. Dr. Josephi, who was the first president of the society, and Dr. Wheeler, secretary from 1889 to 1891, were recently elected honorary president and secretary, respectively. Both physicians took part in the program.

PENNSYLVANIA

Hospital News—Because of a decrease in the number of patients with tuberculosis, the Free Hospital for Consumptives and White Haven Sanatorium Association announced, April 26, that its institutions will be opened to patients with other diseases, including mental ailments.

Cancer Meeting at Altoona—A conference on cancer will be held at Altoona, June 28 under the chairmanship of Dr. William H. Howell. Speakers will include Drs. George W. Crile, Cleveland, on "The Cancer Problem," Bernard P. Widmann, Philadelphia, "Value and Limitation of Roentgen Ray and Radium in Treatment of Cancer," Thomas G. Simonson, Pittsburgh, "Medical Care of the Cancer Patient," and Maxwell J. Lick, Erie, "Tumor of Testicle."

Philadelphia

Hospital News—The Association of Former Interns of the Hospital of the Protestant Episcopal Church held its second reunion at the hospital, April 27. The first was held five years ago and it is planned to continue the gatherings at five year intervals. Dr. Louis H. Mutschler was toastmaster at the banquet, which followed a day's visit to the hospital.

Society News—Speakers before the Obstetrical Society of Philadelphia, May 2, were Drs. George L. Weinstein and Maurice H. Friedman, on "Pharmacological Study of the Uterine Fistula of the Unanesthetized Rabbit," and John H. Harris and Franklin L. Payne, "Value of Irradiation in the Treatment of Ovarian Carcinoma."—Drs. Paul A. Bishop and Paul H. Schraer, among others, addressed the Philadelphia Roentgen Ray Society, May 3, on "Bone Manifestations of Chronic Fluorine."—Drs. Albert A. Martucci and George M. Dorrance addressed the Philadelphia Neurological Association, May 25, on "Diathermy of the Brain in Hemiplegic Patients" and "Management of Spinae Bifidae by Repeated Drainage of the Sac," respectively.

RHODE ISLAND

Society News—Dr. Robert Glen Urquhart, Norwich, Conn., addressed the Washington County Medical Society, April 11 on thoracic surgery.—Dr. Frederic J. Farnell, Providence, gave an address on "Topographical Problems in Brain Tumors" at the State Hospital for Mental Diseases, Howard, March 26.—Speakers at a meeting of the Providence Medical Association, April 2, were Dr. Peter Pimeo Chase, on "Cancer of the Mouth," and Charles J. Smith, D.M.D., diseases of the jaw.—Speakers before the Providence Medical Association May 7, were Drs. Thomas R. Goethals, Boston, on "The Risk to the Infant in Breech Delivery," George Elliott May, Boston, "Dehydration Therapy in the Toxemias of Pregnancy," and Milton Goldberger, Providence, "Sterility Investigations and Findings in Twenty-Four Cases."—Dr. Arthur H. Harrington, Providence, delivered an address on development of psychiatry in America at the State Hospital for Mental Diseases, Howard, May 14.

TENNESSEE

Hospital News—A seventy-five bed addition for Negro tuberculosis patients was dedicated at Oakville Memorial Sanatorium, December 10. The sanatorium is maintained by the city of Memphis and Shelby County.

Radiologic Society Organized—The Tennessee Radiological Society was organized during the annual meeting of the state medical association in Chattanooga, April 10-12. Dr. Charles M. Hamilton, Nashville, was elected president. Dr. Charles H. Heacock, Memphis, vice president, and Dr. Franklin B. Bogart, Chattanooga, secretary. The organization will not only promote radiology but endeavor to present to the profession of the state advances in the knowledge of radiology. It plans to meet yearly during the annual session of the Tennessee State Medical Association.

TEXAS

State Medical Election—Dr. Samuel E. Thompson, Kerrville, was inducted into the presidency of the State Medical Association of Texas at its annual meeting, May 17. Dr. John H. Burleson, San Antonio, was named president-elect, and Dr. Holman Taylor, Fort Worth, secretary. The next annual session will be held at Fort Worth.

Society News—Drs. Arthur C. Scott Jr. and Thelbert T. Bunkley, Temple, among others, addressed the Bell County Medical Society, Temple, April 4, on "Modern Management of Gallbladder Disease and 'Dystocia Fetal and Maternal,'" respectively.—Drs. John M. Triple and John T. Moore, Houston, addressed the Hardin-Tyler Counties Medical Society, Kountze, April 4 on diseases of the prostate and treatment of cancer, respectively.—Dr. Clarence C. Garrett, Fort Worth, among others, addressed the Tarrant County Medical Society, Fort Worth, April 3, on bromide intoxication.

VERMONT

Typhoid Epidemic—Newspapers reported May 3, that forty-six cases of typhoid had occurred at Websterville, near Barre. The infection was traced to the water used in the stricken area and it was believed contaminated material had entered from sewers through drains damaged by the severe winter. One death was reported.

Clinical Meeting—The Vermont State Medical Society held a clinical meeting in cooperation with the University of

Vermont School of Medicine, in Burlington May 4-5 Most of the meetings were held at Mary Fletcher Hospital and were attended by 145 physicians. The faculty committee in charge consisted of Drs Clarence H Beecher, Ernest H Butties and Lyman Allen

WASHINGTON

Public Health Association Formed—Following a public health institute held at Washington State College, Pullman May 4-5, the Washington State Public Health Association was formed with Dr Erval R Coffey, state health officer, as the first president. Among speakers at the institute were Dr James E Drake, Spokane, on control of diphtheria in public schools, and Holland E Wight, DDS, Yakima, on oral hygiene. Dr Platt W Covington, field representative of the Rockefeller Foundation, was the speaker at a dinner meeting.

State Eradicates Bovine Tuberculosis—The U S Department of Agriculture announces that Washington has been designated a modified accredited area in the eradication of bovine tuberculosis. Official tuberculin testing indicates that infection has been reduced to less than 0.5 per cent. Tuberculosis eradication work began in Washington in 1918 and the first county to become a modified accredited area was Waukegan, so designated in 1927. Approximately 2,000,000 tuberculin tests have been applied. Arrangements have been made for retesting in order to eliminate any remaining infection. Washington is the fourteenth state to win this recognition. The states already accredited are North Carolina, Maine, Michigan, Indiana, Wisconsin, Ohio, Idaho, North Dakota, Nevada, New Hampshire, Utah, Kentucky and West Virginia.

WEST VIRGINIA

State Medical Election—Dr Rome H Walker, Charleston, was elected president of the West Virginia State Medical Association at the annual meeting in Huntington, May 14-16. Other officers elected are Drs William W Strange, Huntington, and Robert C Hood, Clarksburg, vice presidents, Thomas M Barber, Charleston, treasurer and Mr Joe W Savage, Charleston, secretary. Wheeling was selected as the place of the meeting in 1935.

WISCONSIN

Meetings of Radiologists—The section on radiology of the State Medical Society of Wisconsin held its tenth annual meeting at the Colonial Club, Janesville, May 18-19. Dr James T Case, professor of radiology, Northwestern University, School of Medicine, Chicago, was the guest speaker. He gave an address at a banquet on "Diagnosis and Treatment of Diverticula of the Gastro-Intestinal Tract" and another at the scientific meeting on "Interesting Gastro-Intestinal Problems."

Dinner to Past Presidents—Drs James C Sargent, Edward L Tharinger and Paul M Currer, Milwaukee, gave a dinner, April 25, to past presidents of the Medical Society of Milwaukee County, with Dr Morris Fishbein, Chicago, editor of THE JOURNAL, as guest speaker. The guests were Drs William P Jobse, Lewis G Nolte, William H Washburn, Arthur J Patek, John J McGovern, Robert G Sayle, Franz Pfister, George H Fellman, Frederick A Stratton, Stanley J Seeger, Charles H Stoddard, Alfred W Gray, Henry J Granling, Ralph P Sproule, Edward L Tharinger, Charles Fidler, Harvey E Webb, Urban A Schlueter, Dexter H Witte and Mr Theodore Wiprud, executive secretary of the society, all of Milwaukee, and Dr Rock Slevster, Wauwatosa. Drs John W Coon, Stevens Point, and Louis T Jernam were unable to attend.

Society News—Dr Hugh Cabot, Rochester, Minn., was the guest speaker at the final meeting of the Milwaukee County Medical Society for the season May 11, on "War Experiences with the Royal Medical Corps." The Milwaukee Professional Men's Orchestra organized a few months ago, made its first public appearance at this meeting. Drs Hilmar G Martin and Herbert G Schmidt addressed the Milwaukee Ophthalmic Society, April 24, on "Biophysics of the Eye" and "The Elsching Intracapsular Cataract Operation" respectively. Dr Louis Hamman, Baltimore, among others, addressed the Medical Society of Milwaukee County, April 13, on "Diagnosis of Obscure Fever." Dr Benn P Churchill presented a paper on "Maxillary and Sphenoid Diseases Compared" before the Milwaukee Oto Ophthalmic Society. Dr Frederick O Tonney, Chicago, addressed the University of Wisconsin Medical Society, May 8, on the diagnosis of amebic dysentery.

GENERAL

Medical Bills in Congress—*Change in Status* H R 3768 has passed the House, changing the name of the retail liquor dealers' stamp tax in the case of retail drug stores or pharmacies to "medicinal spirits stamp tax." *Bills Introduced* H R 9675, introduced by Representative Reece, Tennessee, proposes to provide that any veteran of any war who was not dishonorably discharged, who is in need of hospitalization and is able to defray the expense therefor, may be furnished hospitalization in any Veterans' Administration facility, within the limitations existing in such facilities, on paying a per-diem fee in an amount equal to the average cost of hospitalization per patient day at the facility for the month previous. H R 9727, introduced by Representative Collins, Mississippi, proposes to authorize compensation by the United States to persons disabled by the use of improperly made Jamaica ginger.

American Proctologic Society—The thirty-fifth annual meeting of the American Proctologic Society will be held in Cleveland at the Hotel Cleveland, June 11-12. Speakers will include:

Dr William T Brockman, Greenville, S C, An Atypical or Unusual Attack of Amebiasis.
Dr Edward C Davis, Philadelphia, Is Colitis a Deficiency?
Dr Herbert T Hayes, Houston, Texas, Perirectal Streptococcal Cellulitis.
Dr Rufus C Alley, Lexington, Ky, Rectal Stricture—New Developments in Etiology.
Dr Curtice Rosser, Dallas, Texas, Relation of Anal Fistula to Development of Cancer.
Dr Charles E Howard, Cincinnati, Rectosigmoid Cancer with Extensive Gangrene.

Dr Thomas E Jones and his associates at the Cleveland Clinic Hospital will give an operative clinic and lectures Tuesday afternoon.

Medical Historians' Meeting—The American Association of the History of Medicine will hold its annual meeting in Cleveland, June 11, at the Hotel Carter, in afternoon and evening sessions. The following papers, among others, will be presented:

Dr Victor Robinson, New York, Karl Koller and Anesthesia.
Dr Richmond C Holcomb, Highland Park, Pa, Ruiz Diaz de Isla and the American Origin of Syphilis.
Dr Edward B Krumbhaar, Philadelphia, William Hunter of Newport.
Dr Joseph L Miller, Chicago, Experimental Methods of Claude Bernard.
Otto Glasser, Ph D, Cleveland, Roentgen's Ideals as Reflected in His Letters.
Dr Logan Clendenning, Kansas City, Laryngological Causes of the Great War.
Dr William Gerry Morgan, Washington, D C, Shakespeare's Knowledge of Medicine.

Officers of the association are Drs James B Herrick, Chicago, president; Charles N B Camac, New York, and William S Middleton, Madison, Wis., vice presidents, and Edward J G Beardsley, Philadelphia, secretary.

Conference of Health Officers—The Conference of State and Provincial Health Authorities of North America will be held at the U S Public Health Service Building in Washington, D C, June 5-6. The speakers will include:

Dr Herman N Bundesen, Chicago, Chicago Epidemic of Amebic Dysentery.
Dr George W McCoy, Washington, Epidemiologic and Laboratory Investigations of Amebic Dysentery.
Dr Eugene L Bishop, Nashville, Tenn, Tennessee Valley Health Program.
Arnold Bennett Hall, LL D, of the Brookings Institution, Washington, Public Administration Trends in Relation to Public Health.

Following this meeting will come the thirty-second annual conference of state and territorial health officers with the U S Public Health Service. The program includes the following:

Dr James P Leake, Washington, Epidemic Encephalitis.
Dr Dean Lewis, Baltimore, President American Medical Association, The Quality of Professional Services.
Arthur W Hedrich, Sc D, associate in biostatistics of Johns Hopkins University School of Hygiene and Public Health, Baltimore, Recent Changes in the Incidence and Fatality of Smallpox in the United States.

CORRECTION

The Pay of a First Lieutenant—In THE JOURNAL, May 12, page 1624, under "Physicians Wanted for Civilian Conservation Corps," it was stated that the pay and allowance of a first lieutenant are about \$250 a month. A first lieutenant of the Medical Reserve Corps attached to one of these camps considers that statement misleading. While pleased with the work with regard to the pay he says: "The actual pay that I receive is \$166.47 (this includes the recent 5 per cent increase). From this sum I must pay about \$15 for mess. The approximate pay of \$250 referred to in the article refers only to those officers who have a dependent wife. From this sum there is a deduction of 10 per cent according to the federal economy program."

Pasteurized Versus Raw Milk

It might be supposed that the question of raw versus pasteurized milk had been settled by the practically unanimous pronouncement of the medical profession. But a number of important persons—politicians, agriculturists and even the eminent professor of botany at Oxford, Sir Frederick Keeble, who was controller of the horticultural and food products department of the Board of Agriculture, have attacked the orthodox view in the columns of the *Times*. Their main arguments are that pasteurization impairs the nutritive qualities of milk, that the tuberculosis admittedly conveyed to man by raw milk should be abolished by eradication of the disease in cattle, that diseases other than tuberculosis conveyed by raw milk are unimportant because of their rare occurrence and that there is lack of agreement in the medical profession as to necessity for pasteurization. Lord Dawson, president of the Royal College of Physicians, has replied to these arguments as follows. The excellent project for the eradication of tuberculosis in cattle will take many years. The diseases other than tuberculosis conveyed by raw milk are serious and not infrequent, e. g., septic sore throat, scarlet fever and undulant fever. Within the medical profession there is a consensus for pasteurization perhaps unfamiliar to politicians. The fellowship of the Royal College of Physicians embraces all branches of medicine—not only clinical medicine but also pathology, bacteriology and public health. At the comitia held April 26 the following report was unanimously passed: 1 A daily ration of milk is important for the growth and health of children. 2 The risk of tuberculosis and other diseases following the consumption of raw milk is considerable. 3 Such risk can be obviated by the use of milk submitted to low temperature pasteurization. 4 Such pasteurization does not materially interfere with the nutritive value of milk. The college, while realizing that milk should be produced from cows free from infection and under conditions of cleanliness, recommends (a) that local health authorities should be given power to require that milk sold within their areas should be pasteurized under official control, (b) that steps should be taken to permit the pasteurization and sale, as such, of milk from tuberculin-tested herds, and (c) that, in areas where adequate pasteurization is now impracticable, milk should be boiled before use. Also butter has entered into the controversy. Dr J A Arkwright, bacteriologist of the Lister Institute, said that almost all imported butter, which in 1932 constituted 88 per cent of that consumed in this country, has been rendered free from risk of infection by high temperature pasteurization of the cream before churning. Some English butter has been treated in the same way. Dr Arkwright also pointed out that although living tubercle bacilli may be present in fresh or salt butter or cheese recently made from raw milk, they lose their vitality in these products in from one to eight weeks.

The Milk Marketing Board (a body appointed by the government to control the milk industry) has produced a purer milk scheme, which will come into operation in October, when the new contract period begins. It is proposed to prescribe a standard of purity for milk, and producers who conform to it will receive a bonus on every gallon of milk. Funds for the payment of this bonus will be provided by the levy of a small sum on all producers of milk. The new grade will be termed "accredited milk." The farm, the cow and the milk will be subject to expert examination by local health authorities. The object is not to produce a highly superior grade of milk of

limited quantity but to raise the general standard of milk. It is thought that the majority of producers, attracted by the bonus, will conform to the prescribed standard of purity.

The Human Factor in Road Accidents

Sir Ernest Graham-Little (dermatologist and member of parliament), who is joint chairman of the Road Accidents Parliamentary Group, points out in the *Times* that more than 50 per cent of road accidents are due not to dangerous machinery but to the human factor (the make up of those who operate the machines). Modern psychologic methods have produced reliable tests which show that there are "accident-prone" individuals who are a danger to themselves and to the community. Dr C S Myers, principal of the National Institute of Industrial Psychology, estimates that at least 80 per cent of fatal automobile accidents are due to the human factor. At the National Institute of Industrial Psychology a group of tests have been standardized and found valuable in four separate fields: (1) selecting the best drivers from a number of applicants for a post, (2) selecting the men most suitable for training as drivers, (3) discovering what is lacking in drivers of poor ability in order to remedy deficiencies, if possible, and (4) advising those who intend to learn to drive as to what degree of ability they are likely to develop. In the application of these tests, the following qualities are examined: (1) accuracy, speed and regularity of response to various signals, (2) resistance to distraction, (3) effective distribution of attention, (4) vision and optical defects, (5) ability to estimate correctly the speed, size and distance of other vehicles, (6) readiness to grasp the essentials of a dangerous situation and to respond appropriately, (7) confidence and general road behavior in driving a model car through moving scenery. The apparatus for these tests is simple and cheap and the technique is easy to learn. It is now carried out in certain large automobile schools. Sir E. Graham-Little therefore asks that selective tests should be included in the new road traffic bill.

First Woman Fellow of Royal College of Physicians

For the first time in the 400 years of its existence, the Royal College of Physicians has elected a woman to the fellowship. She is Dr Helen Mackay, physician to the Queen's Hospital for Children, London. She was one of the workers sent out to Austria in 1920 to study the rickets which the war and postwar shortage of food produced. Five years later she investigated the incidence of rickets in London at the request of the Medical Research Council. But her most important work has been on the anemia of infancy. In a report published by the Medical Research Council in 1932 she showed that a form of anemia, not dissimilar to the almost extinct chlorosis of young women, was prevalent among East London infants, whether breast or bottle fed, and was readily curable by administration of iron. The etiology was something of a riddle. Dr Mackay suggested that the anemia might be due to deficient store in the liver or wasteful utilization of iron, or that there might be some controlling factor, comparable to vitamin D. Probably a deficiency of iron in the diet of a pregnant woman would predispose the infant to anemia. The smaller the infant at birth, the greater the likelihood of anemia, for the more rapid the growth relative to the initial weight, the more quickly is the iron store of the liver exhausted.

The Refugees from Germany

The governing body of the High Commission for Refugees from Germany, which was set up by the League of Nations last autumn, has met in London under the presidency of Lord Cecil. Delegates representing Belgium, Czechoslovakia, Denmark, France, Great Britain, Italy, Holland, Poland, Switzerland, Sweden and the United States were present. The high commissioner, Mr James G McDonald, stated that, by nego-

tations, governments had been induced to postpone or soften administrative regulations that would have made the lot of the refugees more difficult, and some countries of potential permanent residence had been persuaded to lessen restrictions on emigration. But the present economic crisis made it impracticable to ask governments to grant general facilities to work to the refugees. Some, however, had given permits to refugees possessing certain qualifications, or organized in cooperative groups, to establish themselves. It was an error to represent the refugees as simply a burden on the countries to which they went. Those who had been permitted to establish a business or industry had brought employment to a number of persons in the country and in some cases had started important new industries. The intellectual refugees constituted a peculiarly difficult problem. The number of academic persons displayed was approximately 1,200, and of these somewhat less than half had actually emigrated. The refugees of the professional group probably totaled more than 3,000. While more than 8,000 students had found it impossible to continue their studies in Germany, about 1,500 had emigrated. Unfortunately, nearly all the academic places that had been found for the refugees were of a temporary nature. In England, fifty refugees had been placed in agricultural schools, and more than 100 had been apprenticed in technical workshops and trades. A number of refugee physicians had been admitted to English and Scottish universities with a view to obtaining in a year's course a medical qualification that would enable them to practice in parts of the British Empire. The larger number of the refugees of an age at which retraining was possible were being prepared for new vocations. The following figures indicate the distribution of the refugees: France, 21,000, Palestine, 10,000, Poland, 8,000, Czechoslovakia, 3,500, Holland, 2,500, England, 2,000, Belgium, 2,300, Switzerland, 2,500, Scandinavia, 2,500, Austria, 800, Saar and Luxembourg, 1,000, Spain, 1,000, Italy, 800, United States, 2,500, other countries, 2,000. Total, 62,400.

The Drug Traffic

The fifth annual report, for 1933, on illicit drug traffic by Russel Pasha, director of the Central Narcotics Intelligence Bureau, shows that in Europe the illegal manufacture of drugs has almost been destroyed and the traffic largely brought under control. But a fresh danger has arisen in the Far East, where in Manchuria a new field of drug traffic is being opened up, which may in time become a menace to the world. What appears to be a government opium monopoly is functioning in Manchuria, and this encourages the growth of the local product and the import of Persian opium. Bulgaria is now almost the only European country manufacturing morphine and cocaine, deliberately designed for illicit traffic. The survival of the manufacture in spite of the ostensible willingness of the Bulgarian government to suppress it seems to be due to the occult influence of various Macedonian organizations. The effects of the limitation of the drug traffic are evident in Egypt, where "white drugs" are now available only in an extremely adulterated form and the traffickers are turning their attention mainly to opium and hashish. The latter comes chiefly from Turkey and Syria, of which the former is the chief purveyor. It is hoped that, owing to the energetic attitude of the Turkish authorities toward the drug traffic, the cultivation of hashish may be gradually controlled. Syria has already taken effective steps to prevent it. A danger arises from the existence in Greece of a large body of professional smugglers, many of whom have been deported from Egypt but still carry on their trade from the Piraeus and the Greek islands. However the Egyptian statistics of drug addicts are striking. On a given date in 1929 there were no fewer than 5,681 addicts among the convicts of Egyptian prisons. On the same date in 1933 the number was only 674.

Silicosis

The Societe d'etudes scientifiques sur la tuberculose pulmonaire devoted a session recently to the discussion of silicosis. Mr. Magnin described the condition as a pulmonary fibrosis resulting from prolonged inhalations of fine siliceous dust. Five years, or even three years, is sometimes sufficient for a workman to develop silicosis. According to Magnin, it is the inhalation of the dust of siliceous rocks, and that alone, which causes pulmonary fibrosis. Pulmonary fibrosis may develop in a person who is already tuberculous. Most commonly, however, pulmonary fibrosis of purely silicotic origin develops in persons who have no history of previous evolutionary tuberculous infection. On the other hand, silicotic fibrosis sometimes reveals a dormant primary infection. Experimentally, it is usually impossible to cause pulmonary fibrosis in an animal until an infection precedes. Finally, from the chemical point of view, the role of free silica in the genesis of so-called silicotic fibrosis of the lung cannot as yet be regarded as fully demonstrated. Recent research by Jones has produced evidence supporting the possible intervention of another substance contained in rocks—sericite. While it is evident that rock dusts are injurious, the damage may not be due to a specific chemical action but rather because they facilitate the development of tuberculous infection. Mr. A. Courcoux referred to the practice in foundries whereby workmen are required to smooth off steel castings in a sand blast, which operation often gives rise to pulmonary silicosis. In some foundries there has been such a high mortality among the workmen, and particularly among those who thus removed the rough places on bicycle parts, that manufacturers have been compelled to supply closed cages, the workmen standing on the outside of these. Since, however, metal tailings have been used for removing rough projections, the untoward manifestations have ceased to develop. Mr. d'Hour reported the peculiar case of a workman in whom a roentgenogram of the lung revealed a granite-like image that pointed to silicosis or granulosis. This man had worked, up to the previous year, in the mines of Nord, at boring in solid rock. Messieurs Rist, Mayel and Donbrow, who studied the question from the medicolegal point of view, are convinced that silicosis cannot develop other than in persons already infected with the tuberculous virus, and hence they refuse to regard it as a true occupational disease, which is in accord with the proposed agreement elaborated by the international bureau of labor. They declare that the acceptance of silicosis as an occupational disease should be avoided by French legislation.

International Federation to Combat Cancer

On the initiative of Mr. Justin Godard and the endorsement of the International Congress on Cancer, held last year in Madrid, a meeting was recently held at the ministry of public health, which was attended by a large number of cancer specialists from various countries, the purpose of which was to prepare the basis of an international federation of the various national leagues against cancer, and to draft a constitution. Justin Godard was elected president. The assembly chose a number of vice presidents: Professor Borst, Germany; Professor Maisin, Belgium; Professor del Rio Hortega, Spain; Professor Wood, United States; Professor Handley, Great Britain; Professor Bastianelli, Italy; Professor de Vries, Netherlands; Nazayo, Japan; Dluska, Poland; Keyberg, Norway; Athias, Portugal; and Dominguez, Cuba. Mr. Bandaline was chosen general secretary. Paris was selected as the headquarters of the federation and as the center for the deposition

of the records, the statistics and other documents of the federation. The triennial session of the officers will be held in a different capital each time to enable them to observe the progress made in each country. Borst, the German delegate, recommended that the new organization, while exercising a general control over the societies existing in the various countries, should respect their independence and should confine itself to supplying suggestions and documentary information. Long discussions were held on the unification of the terminology of tumors and that of statistics. At present, statistics are collected in such a widely different manner that they do not lend themselves to comparison. It was finally decided that every country should be allowed to follow its own custom and that the federation would be content to supply the national societies with a model form for the collection of statistics. The question of publishing an international review dealing with cancer was taken under advisement. It was agreed that the federation should remain associated with the cancer section of the international bureau of health of the League of Nations, with headquarters in Geneva, a section that, in reality, is not particularly active, but it was thought to be impracticable to endeavor to replace it at present. Borst of Germany, however, in conformity with the ideas of the present government of the reich, thought that it might be replaced. The delegates were entertained at two banquets. They visited the cancer institute of the Faculté de médecine de Paris at Villejuif, which is under the direction of Professor Roussy, and the Curie institute, where Madame Curie and Professor Regaud were the hostess and host.

Venereal Disease—Moving Pictures and the Press

In 1927 Germany changed the law pertaining to the combating of venereal disease. In the intervening period a number of changes have been made. The law has had a good effect. In spite of the unquestionable retrogression of venereal diseases, and particularly of syphilis, there is still a large proportion of the population of Germany affected with venereal disease. Detailed statistics on the subject were given in a previous letter (*THE JOURNAL*, January 13, p. 144). In October 1927 the central government took over the combating of venereal disease, which had previously been left to the *Gesellschaft zur Bekämpfung der Geschlechtskrankheiten*. During the twenty-five years of its existence this society had collected the basic statistics needed for an understanding of the status of venereal disease in Germany. Prof. J. Mayr, the director of the Freiburg Klinik für Haut- und Geschlechtskrankheiten, brought out before the Freiburg Medical Society that recent months have witnessed the launching of a publicity campaign among the young persons who belong to the various political leagues of the S. A., the S. S., the Stahlhelm, the work camps, and the like. Mayr emphasized that the law in its present form, has no teeth in it, as it does not provide penalties. Then it was found that this law furnished no adequate means of checking prostitution through the suppression of "street walking," whereas the new government, through an effective recasting of the paragraph in question, has been able to carry on a vigorous crusade against prostitution. It appears desirable to make the notification of venereal disease obligatory in Germany. The proposed plan of having certain mergers of societies take over the expense of treatment is commendable, since only by such means will it be possible to get quickly in touch with persons having venereal disease and to effect their cure—at least to the extent that they will no longer be a menace. In addition, all measures will be supported that tend to strengthen the sense of sexual responsibility, especially among the youth.

Professor Uhlenhuth emphasized the need of adopting strict measures with reference to race hygiene, or eugenics. The tragic decline in the birth rate is due in part to the widespread incidence of venereal disease. Fifty per cent of all childless and one child marriages point to gonorrhea in at least one spouse. Gonorrhea is responsible for the loss of 200,000 births annually, without attempting to measure precisely the baneful effects of syphilis. If the notification of venereal disease should be made compulsory, suspicious persons would be brought in at once for medical examination, for at present the demand that they present a medical certificate often causes such persons to change their residence, whereby the authorities lose sight of them. The result is that new foci of infection are established. A search for the source of a new infection cannot be instituted unless a special request is made, and many persons refuse to make such a request for fear of unpleasant experiences. To raise the standard of morals in matters of sex, other things are needed. The elimination of trashy and vicious literature as presented in word and picture, and a general purification of the press, the motion picture houses and the bars would be a pleasing beginning. Energetic efforts should be made to check clandestine prostitution. Uhlenhuth emphasized that present conditions are absolutely unbearable and constitute a great menace to youth, particularly in the university cities. The rendezvous taverns and hotels should be abolished. It appears doubtful whether it will be possible, in harbor and university cities, to dispense entirely with restricted districts. In Bremen, prostitutes are permitted to rent, on their own account, certain houses in certain streets, where they are subject to medical and police control but are not exploited by professional brothel keepers. In some countries (America and Hungary) such methods are being reintroduced.

Allergy in Relation to Rheumatism

Rheumatism in the conception of today was unknown to ancient medicine, as Prof. Ludwig Aschoff of the University of Freiburg pointed out before the Medical Society of Freiburg im Breisgau. An endeavor must be made to separate from the confused mass of rheumatic disorders those in which etiology is known or, if unknown, those which are of a specific nature. Among the specific disorders may be classed acute articular rheumatism. All attempts to discover the causative agent have thus far been fruitless. In Aschoff's opinion the causative agent is not to be sought in any known streptococcus. All attempts to explain the origin of specific nodules as due to allergic reaction are of no avail. The nodule formations occurring after direct injection of the joints or intravenous injection are not of a specific nature. The nodules that develop in the heart muscle or elsewhere following intravenous injection may have a similar appearance but the proof of identity is lacking. Aschoff stated that naturally, in so called serum horses that are being constantly injected with doses of toxin, the joints that are weight bearing in the standing posture, and particularly the extremities, may show evidence of damage due to toxins. Thus the well known forms of serum arthritis may arise, but these have nothing to do with so called rheumatic disease. They cannot, however be termed allergic diseases but at the most, arthritis with allergic symptoms. The conditions are similar with respect to asthma and the so called allergic disorders of the upper air passages. Here it might be more accurate to speak of pollen bronchitis with allergic symptoms. In any event, all these allergic disorders have nothing to do with the rheumatic diseases.

The attempt to include arteriosclerosis among diseases of a rheumatic nature is not justified. Aschoff called attention to conditions in Java where arteriosclerosis is common but genuine articular rheumatism or rheumatismus specificus infectiosus rarely occurs among natives. Aschoff emphasized how necessary

it is to investigate the etiology of all so called rheumatic disorders. Such etiologic research appears to him to promise better results than nosologic research. The cause of the confusion lies in the fact that a clinical symptom has been chosen for various disorders that are etiologically entirely different. The disorder should be named from the etiologic point of view, and in every disease a type with rheumatic symptoms should be distinguished from one in which rheumatic symptoms are lacking.

Roentgen Safety Films

Roentgen safety films possess advantages over the celluloid films in that they are not easily ignited when exposed to a flame, nor are they easily decomposed by heat. They burn only in a strong air current and smolder only when exposed to great heat. Burning safety films can ordinarily be extinguished by blowing on them and easily by pouring water over them. In quantity and composition the decomposition gases of safety films are no more dangerous than those arising from burning paper, wood or blankets.

The federal minister of the interior has announced that users of these films will be relieved of the necessity of adopting the special safety measures made necessary by the menace of celluloid films. Comparing the relative danger of celluloid films and of safety films, it is stated that the storage of safety films constitutes no more of a fire menace than the storing of paper documents.

March 31, 1934

Congress of Orthopedics

The Società italiana di ortopedia held its twenty-fourth national congress at Palermo. Prof. Enrico Ettore said that the fundamental principles of the treatment of fractures are early and accurate reduction, absolute immobilization of the focus until complete consolidation of the callus has occurred and active mobilization of the joints. In fractures of long bones, the treatment comprises direct traction on the skeleton with a wire, applied as early as possible with the limb in an easy position, so as to obtain the greatest muscular relaxation. The reduction having been taken care of, immobilizing appliances are applied, which permit the continuation of traction on the double inclined plane without any secondary displacement. Absolute immobility of the focus of the fracture is indispensable, but it is no longer permissible to enclose a limb in a plaster cast and await consolidation. Modern treatment is understood in an active sense, and muscular contraction is worth more than any passive movement and helps more to maintain muscular tone than do electric currents. The period of traction is reduced to what is absolutely necessary, apparatus being applied that is capable of maintaining the reduction while permitting the patient to walk. Open treatment of fractures has lost ground everywhere. In fractures of the spinal column the speaker is opposed, save for certain rare exceptions, to any intervention whether surgical or reductive. In fractures of the neck of the femur, when bloodless or operative treatment (Smith-Petersen nail extension) does not inspire sufficient confidence, he favors subtrochanteric osteotomy, which if applied in time enables the patient to walk within four months of the accident.

Boehler of Vienna illustrated with films and with presentation of apparatus the various methods of treatment employed by him in fractures and luxations of the various parts of the skeleton. For fractures of the spinal column he is an advocate of reduction performed under local anesthesia.

Palagi, on the basis of statistics of the Clinica ortopedica of Florence which during the past eight years comprised sixty-seven cases of fracture of the upper end of the femur is an

advocate, in intracapsular fractures, of bloodless treatment, which permitted him to secure definitive consolidations in 76.5 per cent of the cases.

Rapaccini reported that in the Istituto ortopedico toscano in forty-six cases of fracture of the shoulder satisfactory results were obtained by the employment of the bloodless method, with abduction and external reduction of the arm and anteposition of the elbow.

Fusari of Turin reported on forty-one birth traumatism (namely, twenty-eight fractures and thirteen epiphyseal displacements). Epiphyseal detachments are considered grave. The fractures have an almost constant site, namely, at the middle third of the humerus and between the middle third and the upper third of the femur. In certain cases of birth fracture, open reduction and osteosynthesis give good results.

Rocher of Bordeaux discussed myositis ossificans progressiva. He said that one can secure an arrest of the ossifying process through action on the parathyroid apparatus. If the calcemia is not modified, removal of the osteomas is followed by a rapid recurrence.

The second topic, "Arthrodesis in Osteo-Articular Tuberculosis," was discussed by Professor Zanoli. He brought out that the basic treatment, so long as there is an active tuberculous focus, remains orthopedic treatment and heliochymotherapy. The new surgical trend (return to arthrodesis) has, however, gained ground in recent years.

Osteosynthesis of the spinal column has been on trial for more than twenty years. The consensus is almost unanimous. The ankylosing operation on the spine may be considered under two types: the Albee method and the Hibbs technic. The former is the preferred method for the treatment of Pott's disease.

In lesions of the hip, statistics give 88.7 per cent of good results from arthrodesis in a series of 700 cases. The operative methods are numerous. The prevailing tendency is to reserve arthrodesis for the sequels of coxitis, and to avoid resorting to it in the evolutionary types occurring in children. In incomplete and painful ankylosis of the knee, arthrodesis by inflexion was recommended, but resection is preferable. As to the foot, the speaker, in cases of tuberculosis localized in the tibiotarsal joint, tried arthrodesis by nail extension and also the extra-articular method. He found the latter preferable.

Fiorentini of Milan spoke on the remote outcome of vertebral osteosynthesis in tuberculous spondylitis and concluded that osteoplastic fixation of the vertebral column is effective but should not cause one to neglect the many other general and orthopedic aids. Mezzari performed arthrodesis in fifty-four cases, involving mostly the hip, in cases of osteo-articular tuberculosis. He had a high percentage of definitive recoveries.

Pacini, in forty-seven spondylitic patients treated by arthrodesis, reexamined them from two to six years after intervention and found good clinical and roentgenographic results.

Calandra of Palermo spoke on the treatment of articular tuberculosis with a new method that he applies in specific types involving the knee. It consists of injections of alcohol at a temperature of 90° C in the region of the nerves and vessels of the diseased joint. He secured favorable results in three cases. As the treatment is recent and the cases thus treated are few, the speaker refrains from drawing any final conclusions.

A New Academician

Prof. Pietro Rondoni, of the department of pathology at the University of Milan, was recently named "academician of Italy." Professor Rondoni, born in 1882, is the author of many scientific works, which in his earlier years dealt chiefly with morphology. Particular interest attaches to his serologic researches, in which he studied various problems pertaining to the Wassermann reaction, studies on trypanosomiasis, allergic inflamma-

tion and the histologic peculiarities of experimental tuberculosis, and pellagra and other diseases due to defective diets. He was the first to call attention to the involvement of the suprarenals in experimental scurvy. His treatise on biologic chemistry appeared recently in a second edition.

Professor Albertoni

Senator Pietro Albertoni, professor emeritus of physiology at the University of Bologna, has died. Three years after graduation, he became instructor in physiology at the University of Siena. He held later a chair in pharmacology, first at Genoa and then at Bologna. He succeeded Augusto Murri in the management of the *Clinica medica*. There is scarcely a field of physiology or pharmacology in which Albertoni had not done research. Special merit attaches to his researches on the digestive tract, the heart and the nerve centers. From his school have gone many students who have occupied chairs in Italian universities. Albertoni was the editor of the scientific periodicals *L'Universita*, *Bollettino delle scienze mediche* and *L'Universita Italiana*.

VIENNA

April 10, 1934

A Test Serum for the Blood Groups M and N

The discovery of the two blood groups M and N has confronted scientists with problems that have been particularly difficult, owing to the fact that the new blood groups form no antibodies in the human blood. For that reason, too, the mixture of M blood with N blood during a transfusion does not constitute a menace. After much research, Prof. Dr. M. Eisler of the *Staatliches Serotherapeutisches Institut* in Vienna developed a useful test serum from the blood of rabbits. But this serum could be preserved only a short time, so that it was not practical, for instance, in connection with court proceedings. Now Eisler has produced a test serum that can be preserved for at least one year and is suitable for transportation. This serum can be used for the determination of parenthood. To the previously known blood groups A, B, AB and O, three new groups have been added, namely, M, N and MN. Comprehensive investigations on more than 1,000 families and more than 3,000 children have shown that likewise the newly discovered blood groups are inherited in accordance with definite laws. If the blood group M or N is present in the blood of the parents, it will be found without exception in the blood of the children of that union. It is, for example, impossible that a child with the M blood group should have parents with the N blood group. In that case, therefore, in connection with court proceedings to establish the paternity of a child, a father with the N group can be excluded. The determination of the M and N groups alone is sufficient to divert suspicion from a suspected father in 18 per cent of the cases. In combination with A and B group, the number of positive results is increased to 31 per cent. Thus, this production of stable and ready-to-use test serum M and N in Vienna makes possible its use in general legal practice for the determination or rejection of paternity.

The Problem of Artificial Nutrition

Addressing the Vienna *Medicinisches Doktorenkollegium*, Dr. W. Lapp gave an exposition of the essentials of artificial nutrition. Emergency nutrition through the esophageal or nasal sound or a gastric or intestinal fistula can be carried on for an extended period. The foods must be seasoned in the same manner as would be necessary for the normal palate in order to maintain an equilibrium of the secretory activity. An adequate supply of vitamins must be introduced in case the normal food lanes remain impassable for some time. With the esophageal or the nasal sound, about every two hours, fluids are

introduced such as *café au lait*, bouillon with egg, oatmeal soup, mixtures of milk, cream, egg yolk and sugar, wine with egg, barley soup and the like. Between meals, fruit juices freshly prepared and sweetened should be given. Through a gastric fistula, more solid foods may be introduced. If hydrochloric acid is present in the stomach in normal quantities, one may follow an almost normal diet. If there is an acidity, the proteins should be reduced to a minimum and uncooked foods should be entirely omitted. One may introduce 2,500 calories in the form of the *au lait* (a mixture of tea and hot milk), oatmeal soup with egg, cream, cocoa, barley soup and sago, with suitable preparation. If it is a question of an intestinal fistula following jejunostomy, one must not count on the digestive activity of the stomach and, as in the gastrostomy diet in achylia, one should follow the diet just given. The narrow lumen of the intestine permits the introduction of only a small quantity of fluid at a time, which should be infused slowly, because of the danger of retrogressive peristalsis.

Rectal feeding will not furnish adequate nutrition over a long period. In the lower intestine, the resorption of fat and proteins is uncertain. Meat juices, eggs, milk, blood derivatives, casein and pulverized vegetable protein should be omitted from the nutritional *clysmas*. Albumoses and peptones can be resorbed, but, as a rule, the irritation is greater than the beneficial effect. The mucous membrane of the large intestine being poor in ferments, it is powerless when called on to digest normal fats, with the possible exception of egg yolk fat. Only isotonic fluids such as salt and dextrose solutions are resorbed without irritation, preferably in the form of a drip *clysmas*. As a nutritional *clysmas*, one may give a mixture of 10 per cent dextrin, 3 per cent alcohol and 0.7 per cent sodium chloride to 1 liter of water. In the presence of bleeding gastric ulcer, even such a *clysmas* may be injurious, owing to reflexive stimulation of the production of gastric juice. Nutrition by means of a duodenal sound is suitable only in psychogenic, incoercible vomiting, but it is often just as useless as the other methods of artificial nutrition (percutaneous, parenteral, which have no practical value).

Operative Treatment in Tuberculosis of the Bones

Dr. Erlacher of Graz delivered an address on the results obtainable by surgical interventions in tuberculosis of the bones and joints. On the series of 420 patients 700 interventions were performed. The patients were under observation from 1919 to 1933. In fifty-eight cases operative evacuation of the tuberculous focus was resorted to—a total of eighty-seven foci. Whereas of 207 cases treated conservatively nineteen ended fatally (the patients were all children under 14 years of age), of the patients operated on only three died, and these died from intercurrent diseases that had no connection with the operation. In not one of the cases observed could a dissemination of the tuberculous disease as a result of the operation be demonstrated. The cases treated conservatively showed a mortality four times as high as those in which an operation was performed. Of the latter group, twenty-eight patients have presented no recurrence after the lapse of five years, and a few patients have been under observation for thirteen years, and their cure appears to be permanent. The functional results are excellent. Of twenty-nine 'joint cases,' nineteen present joints that have entirely normal movements—one hip joint, four knee joints and four elbow joints. In only four cases did stiffness remain as before the intervention. The tuberculous nature of the disorder was clearly established in all cases by animal experiments or histologic examination.

The advantage of operative over conservative treatment is apparent from the economic point of view. Conservative treatment of the hip or knee covers a period of about four years. In the case of small bones and joints, two years is the average,

whereas a spine requires six years of conservative treatment to be cured. The operation, on the other hand, may remove all tuberculous tissue, so that definitive recovery usually is effected within one year. In only eight cases was the period of healing after the operation more than two years. Erlacher recommends as imperative the earliest possible operative evacuation of the bone or joint focus—that is, in early childhood if possible. In the choice of operative cases, due consideration must be given to the general condition of the patient.

Wenckebach's Birthday

The internist Karl Friedrich Wenckebach celebrated his seventieth birthday March 24, being in complete possession of his physical and mental vigor. Professor Wenckebach was born in the Netherlands. His first intention was to become a zoologist, but he soon turned his attention to medicine. While a practitioner in a rural district, he devoted himself to studies on cardiac conditions, especially arrhythmia. He published from this field a number of observations that attracted attention and procured for him in 1902 the chair of internal medicine at the University of Groningen. Nine years later he was called to the University of Strasbourg. In 1914 he accepted a post in Vienna as the successor of von Noorden, where he took charge of the first clinic and transformed it into a European center for cardiac research. The "Wenckebach Klinik" soon acquired an international reputation. His studies on arrhythmia, angina pectoris, "Wenckebach's bundle" "thorax piriformis Wenckebach" and "heart changes in beriberi," which he carried on in Batavia under a commission from the government of the Netherlands, established his fame on a firm basis. At the age of 65 he resigned his post as clinical teacher to do research exclusively.

Death of Schlesinger

Prof. Dr. Hermann Schlesinger, an eminent scientist and a great patron of art, has died, aged 67. Schlesinger was early recognized as a physician of unusual ability. His career has been brilliant. Nothagel, who at that time (1890-1900) was an authority in internal medicine, summoned him to Vienna as first assistant in his clinic. At this time he had begun his studies on syringomyelia. He devoted himself also to the study of tetany described by the syphilitic disorders of the vascular system and made researches on the pathology of tuberculosis. As head of a large department of the Vienna General Hospital, he founded what he termed a "Lehr- und Heil-Schule," which, at the time of the medical nihilism in therapy, gave a definite trend to thought. From this research center came a work that is still regarded as authoritative, "The Diseases of Old Age." During the war he established a large institute for the treatment of pulmonary tuberculosis, which is still functioning. In addition to his activity as scientist, teacher and physician he found time and leisure as a patron of art, to found the Theatrumuseum. In order that his work might not be left unsponsored, Docent Dr. Holler, a pupil and assistant of Professor Ortner, has been appointed successor to Schlesinger.

Marriages

THOMAS FORD HUEL JR., Anniston, Ala. to Miss Sybil Parrish Flowers of Durham, N. C., April 21.

KENNETH HERBERT HAMMOND Hoopeson, Ill., to Miss Martha Hugus of Gary, Ind., April 27.

VINCENT C. NIPPLE, Midvale, Ohio to Miss Lucy Schoonover April 22.

CARL GOLDBARK JR. to Miss Hazel Seligman both of New York, May 11.

SHELLEY C. DAVIS to Miss Ethel York both of Atlanta Ga., May 26.

Deaths

Charles Winfield Pilgrim, New York, Bellevue Hospital Medical College, New York, 1881, member of the Medical Society of the State of New York, member of the American Psychiatric Association, at one time chairman of the State Hospital Commission, past president of the New York Academy of Medicine, superintendent of the Willard (N. Y.) State Hospital, 1889-1893 and the Hudson River State Hospital, Poughkeepsie, 1893-1906, medical superintendent of Dr. MacDonald's House, aged 79, died, May 3, at his home in Central Valley.

John Forest Dickson, Berkeley, Calif., University of Toronto Faculty of Medicine, Toronto, Ont., Canada, 1880, member of the American Academy of Ophthalmology and Otolaryngology and the Pacific Coast Oto-Ophthalmological Society, fellow of the American College of Surgeons, member of the Oregon State Medical Society, emeritus professor of ophthalmology, University of Oregon Medical School, Portland, aged 78, died, April 3.

William A. Clark, Jefferson City, Mo., Washington University School of Medicine, 1897, past president of the Missouri State Medical Association and the Cole County Medical Society, past president of the state board of health, fellow of the American College of Surgeons, on the staffs of the Masonic Hospital, St. Louis State Hospital, number 1, Fulton and St. Mary's Hospital, Jefferson City, aged 68, died, April 11, of pneumonia.

Joseph Ellsworth Toot, East Liverpool, Ohio, University of the City of New York Medical Department, 1890, member of the Ohio State Medical Association, formerly on the staff of the East Liverpool City Hospital, aged 72, died, April 13, of angina pectoris, arteriosclerosis and hypertension.

Neil L. Goodrich, South Haven, Mich., University of Michigan Homeopathic Medical School, Ann Arbor, 1906, past president of the Kalamazoo Academy of Medicine, on the staff of the City Hospital, aged 53, died suddenly, March 25, in the Blodgett Hospital, Grand Rapids, of coronary thrombosis.

Theodore Parker Simpson, Beaver Falls, Pa., Bellevue Hospital Medical College, New York, 1877, fellow of the American College of Surgeons, member of the surgical staff of the Providence Hospital, Beaver Falls and the Beaver Valley General Hospital, New Brighton, aged 77, died, March 5.

Lawrence Boykin Hudson, Hattiesburg, Miss., Tulane University of Louisiana Medical Department, New Orleans, 1907, fellow of the American College of Surgeons, on the staff of the Methodist Hospital, aged 51, was accidentally shot and killed, April 18, while hunting in the woods.

Charles Mills Herald, Elyria, Ohio, Western Reserve University School of Medicine, Cleveland, 1916, fellow of the American College of Surgeons, on the staff of the Elyria Clinic and Elyria Memorial Hospital, aged 46, was found dead in his office, April 19, of heart disease.

James Edward Dickinson, Harrisburg, Pa., University of Pennsylvania School of Medicine, Philadelphia, 1899, for many years president of the city board of health, formerly member of the state legislature, on the staff of the Harrisburg Hospital, aged 58, died, March 12, of uremia.

Fred Hann Carver, Waitsburg, Wash., Medical Department of Washington University, 1901, member of the Washington State Medical Association, aged 56, died, February 28, of injuries received when his automobile plunged off the highway, presumably while he was asleep.

William Latane Varn, South Hill, Va., Medical College of Virginia, Richmond, 1915, member of the Medical Society of Virginia, past president of the Mecklenburg County Medical Society, aged 42, died, March 21, in the Richmond (Va.) Hospital, of streptococcal septicemia.

R. E. Thompson, Inman, S. C., Atlanta (Ga.) Medical College, 1875, member of the South Carolina Medical Association, formerly member of the state legislature, aged 84, died March 9, in a hospital at Spartanburg, of arterial hypertension and cerebral hemorrhage.

Walter Glenn Graham, Pittsburgh, University of Pittsburgh School of Medicine, 1911, member of the Medical Society of the State of Pennsylvania, aged 50, died, March 19, in the Passavant Hospital of heart disease during nephrectomy performed under spinal anesthesia.

Addison Eugene Elliott, San Diego, Calif., Rush Medical College, Chicago, 1908, fellow of the American College of Physicians, member of the American Roentgen Ray Society,

and the Radiological Society of North America, aged 57, died, April 9, of heart disease

Robert Daniel Tucker, Powhatan, Va, Medical Department of Columbian University, Washington, D C, 1892, member of the Medical Society of Virginia, president of the Powhatan County Medical Society, aged 73, died, March 13, of heart disease

Lauren Eugene Flickinger, Canton, Ohio, Western Reserve University Medical Department, Cleveland, 1892, member of the Ohio State Medical Association, on the staff of the Aultman Hospital, aged 65, died, March 25, of cerebral hemorrhage

Joseph Arthur Valenta @ Cedar Rapids, Iowa, State University of Iowa College of Medicine, Iowa City, 1896, aged 63, formerly on the staffs of the St Luke's Methodist Hospital and Mercy Hospital, where he died, March 17, of mitral stenosis and myocarditis

Burton N Clark @ Oshkosh, Wis, Rush Medical College, Chicago, 1894 past president of the Winnebago County Medical Society aged 66, on the staffs of St Mary's Hospital and the Mercy Hospital, where he died, April 18, of carcinoma of the bladder

James Edmund Dorsey, Boston, Harvard University Medical School, Boston, 1878, member of the Massachusetts Medical Society aged 80, died, March 13, in the Massachusetts General Hospital, of cerebral thrombosis and arteriosclerosis

Eli Slifer Walls @ Pittsburgh, University of Pennsylvania School of Medicine, Philadelphia, 1909, fellow of the American College of Surgeons, member of the visiting staff of St Francis Hospital, aged 52, died, March 28, of coronary occlusion

Kittie Plummer Gray, Portland, Ore, University of Oregon Medical School, Portland 1900 member of the Oregon State Medical Society aged 69, died, March 27, in the Good Samaritan Hospital of cerebral hemorrhage and arteriosclerosis

Blanche Edith Webber @ Chicago, Harvey Medical College Chicago, 1902 College of Physicians and Surgeons of Chicago, School of Medicine of the University of Illinois, 1903, aged 67, died, April 18, of coronary thrombosis

Julian Hiland Dewey @ Philadelphia, University of Pennsylvania School of Medicine, Philadelphia, 1891, fellow of the American College of Surgeons, ophthalmic surgeon to St Francis Hospital Trenton, aged 66, died, March 30

Charles William White, Covington, Ky, Hospital College of Medicine, Louisville, 1894, at one time health officer of Covington, formerly on the staff of the Booth Memorial Hospital aged 62, died March 13, of myocarditis

Eddie Timothy Hollingsworth @ Goldsboro, N C, North Carolina Medical College, Charlotte 1912 formerly member of the state board of health, on the staff of the Goldsboro Hospital, aged 46, died, May 7, of angina pectoris

Charles Eugene Chappell, Marne, Mich, University of Michigan Medical School, Ann Arbor, 1885, formerly member of the board of education, aged 79, died, April 7, of cerebral hemorrhage, myocarditis and arteriosclerosis

Orley Morton Waters, East St Louis, Ill, St Louis University School of Medicine 1920, member of the Illinois State Medical Society, aged 50, on the staff of the Christian Welfare Hospital where he died, March 14

Andrew James Ames, Fargo, N D, University of Illinois College of Medicine, Chicago, 1901, on the staff of the Veterans' Administration Facility for many years, aged 68, died, April 12, of cerebral hemorrhage

Daniel Hurst Carns, Albuquerque, N M, Western Pennsylvania Medical College, Pittsburgh, 1894 member of the New Mexico Medical Society, aged 64, died, March 30, of angina pectoris and diabetes mellitus

James Rufus Liverman, San Bernardino, Calif University of Arkansas School of Medicine, Little Rock, 1900, aged 68, died, March 16 of hypostatic pneumonia, injury to the head and fractured forearm

Stephen L White, Seymour, Mo, St Louis College of Physicians and Surgeons, 1883 also a minister aged 73, died March 13, in Rochester, Minn, of hypertrophy of the prostate and pyelonephritis

Joel Audubon Webb, Providence, R I University of the City of New York Medical Department, 1889, member of the Rhode Island Medical Society, aged 79, died, February 20, of cerebral hemorrhage

William H Stiles, San Bernardino, Calif, Hahnemann Medical College and Hospital, Chicago, 1878, member of the

California Medical Association, aged 80, died, March 25, of cerebral hemorrhage

James T Hanson, Gallipolis, Ohio, Medical College of Ohio, Cincinnati, 1874, county coroner, aged 83, died, April 20, in the Holzer Hospital, of a skull fracture received in an automobile accident

Perry Lawson Ferry, Akron, Ind, Cornell University Medical College, New York, 1904, served during the World War, aged 54, died March 30, in McDonald Hospital, Warsaw, of pneumonia

Lillian Atkins Moore Clark, Philadelphia, Woman's Medical College of Pennsylvania, Philadelphia, 1923, member of the Medical Society of the State of Pennsylvania, aged 36, died, March 21

Willis Monroe Metzler, Vanlue, Ohio, Starling Medical College, Columbus, 1895, member of the Ohio State Medical Association, aged 67, died, March 12, in the Home and Hospital, Findlay

Edwin Daniel Townsend, Eastland, Texas (licensed in Texas under the Act of 1907) member of the State Medical Association of Texas, aged 72, died, March 20, of cerebral hemorrhage

Charles Clifford Bennett, Smith Center, Kan, University Medical College of Kansas City, 1913, member of the Kansas Medical Society, aged 43, died, April 26, of a self inflicted bullet wound

Charles Franklin Keyser, Cuyahoga Falls, Ohio, College of Physicians and Surgeons, Baltimore, 1886, member of the Medical Society of the State of Pennsylvania, aged 73, died March 10

Charles Ernest Tran, Kamsack, Sask, Western University Faculty of Medicine, London, Ont, Canada, 1912 served during the World War, formerly mayor, aged 52 died March 23

Achille Besner, Valleyfield, Que, Canada, School of Medicine and Surgery of Montreal, 1897 coroner for the district of Beauharnois, aged 62 died suddenly, February 15 of angina pectoris

Marvin Sumter Witt, Manchester, Ga Atlanta Medical College 1914, member of the Medical Association of Georgia aged 48, died March 3, in the Piedmont Hospital Atlanta

Charles Cogley Marshall, Aurora, Ind Medical College of Ohio, Cincinnati, 1897, served during the World War, aged 60 died March 12, in the Dillsboro (Ind) Sanitarium

Herman Lee Hildreth, Julian, Calif Bennett College of Eclectic Medicine and Surgery, Chicago, 1900, member of the California Medical Association, aged 58, died March 7

William Peyton Barton @ Portland, Ore Tulane University of Louisiana Medical Department, New Orleans 1904 aged 53 died April 27, of a self inflicted bullet wound

David Ber Domb, San Francisco, Indiana University School of Medicine, Indianapolis, 1909, aged 53 died, March 24, in the Stanford University Hospital, of myocarditis

Clarence Hyde Saunders, Chase City, Va College of Physicians and Surgeons Baltimore, 1891 member of the Medical Society of Virginia aged 63, died March 14

William Edward Cook @ Pageton, W Va Medical College of Virginia Richmond, 1901, served during the World War, aged 63, died, May 5, of chronic myocarditis

Leo Ervin Oscar Evens, Hartford Conn St Louis College of Physicians and Surgeons, 1897, member of the Iowa State Medical Society, aged 61, died, March 26

James D Harlan, Fairfield Ill, Missouri Medical College, St Louis, 1890, member of the Illinois State Medical Society, aged 72, died April 28, of organic heart disease

Levi Daniel Johnson, Whittier, Calif Bennett College of Eclectic Medicine and Surgery Chicago 1888, Atlanta (Ga) Medical College, 1897 aged 78 died, March 3

William Black, Winnipeg, Manit, Canada, Manitoba Medical College, Winnipeg 1903 served during the World War, aged 53 died, April 3 of cerebral hemorrhage

John B Deal, Crockett, Texas, Baylor University College of Medicine Dallas, 1913 member of the State Medical Association of Texas, aged 46 died March 2

F R Wallace, Cordele, Ga, University of Georgia Medical Department, Augusta 1879 member of the Medical Association of Georgia aged 77, died January 13

Allen Earl Gray, Marysville, Calif, Cooper Medical College, San Francisco 1911 member of the California Medical Association aged 46, died, March 16

Isaac Adal McCarty ☉ Los Angeles, St Louis College of Physicians and Surgeons, 1883, aged 74, died, March 23, of angina pectoris and arteriosclerosis

George W Darling, Portsmouth, Ohio, Hospital College of Medicine, Louisville, Ky, 1885, formerly postmaster of Wellston, aged 87, died, March 16

Orville Augustus Rhodes, Salem, Ohio, College of Physicians and Surgeons, Baltimore, 1882, aged 72, died March 16, in the City Hospital, of uremia

Griswald Bragaw, Milford Conn, Bellevue Hospital Medical College, New York, 1897, aged 68, died, Dec 26, 1933, of adenoma of the prostate

David De Tar, Winslow, Ind (licensed in Indiana in 1897), Civil War veteran, aged 88, died, April 20, of lobar pneumonia and chronic endocarditis

Thomas Henry McDonough, Frenchtown, N J, Medical School of Maine, Portland 1898, aged 59 died, March 29, of carcinoma of the esophagus

Henry William Kauffold ☉ Frankenmuth Mich, Vanderbilt University School of Medicine, Nashville, Tenn, 1917, aged 39, died, March 18

Felix Cornu, Buckingham, Que, Canada, Victoria University Medical Department, Coburg, 1887, aged 68, died, January 29, in Montreal

Thomas Dowe Allen, Shaw, Miss (licensed, Mississippi in 1903), aged 57, died, March 29, in the Kings Daughters' Hospital, Greenville

Peter D Arbogast, Morgantown W Va University of Virginia Department of Medicine, Charlottesville, 1901, aged 67, died, March 31

James Ozwill Nicholson, Lead Hill, Ark Memphis (Tenn) Hospital Medical College, 1900, aged 58 was found dead, February 27

Frederick Charles Delahey, Pembroke, Ont Canada University of Toronto Faculty of Medicine, 1895, aged 63, died, February 8

Francis Henry Bermingham, Kingston Ont, Canada Queen's University Faculty of Medicine, Kingston, 1892 aged 63, died, May 1

Henry Powell Halsted, Perry, Mich, University of Michigan Medical School, Ann Arbor, 1877, aged 83 died, April 11, of senility

J Esdras Beaudet, Deschailions, Que, Canada Laval University Faculty of Medicine, Quebec, 1899 aged 61, died, February 28

John T Smith, Georgetown, Tenn University of the South Medical Department, Sevanee 1899, aged 65, died, March 17

Thomas Wright Reagan, Union, Miss, University of Nashville (Tenn) Medical Department, 1908 aged 49, died, March 19

Whitley Gray Hendrix, New London, Mo, College of Physicians and Surgeons, Keokuk, Iowa 1871, aged 91, died in March

Russell Bayly, New York St Louis Medical College, 1877, aged 81, died, April 22, in the Bellevue Hospital, of arteriosclerosis

Henry Schumacher, Walcott, Iowa State University of Iowa College of Medicine, Iowa City, 1882, aged 77, died March 4

Bureau of Investigation

SOME NOSTRUMS IN RETROSPECT

Condensed Reports on Widely-Advertised "Patent Medicines"

The Bureau of Investigation of the American Medical Association receives thousands of inquiries every year from physicians and laymen asking for information on "patent medicines" and quacks. The chief work of the Bureau consists in answering these inquiries. Naturally, the bulk of the questions that come in deal with nostrums that loom large in the public eye at the time of the inquiry. The material that follows represents condensed restatements of more extensive articles that have been published in the past in this department of THE JOURNAL dealing with preparations about which the Bureau still receives many inquiries. It is reasonable to believe that for every letter that the Bureau gets from a physician or layman about an advertised "patent medicine," there are probably a dozen laymen and an equal number of physicians who are interested in getting such information but do not take either the time or the trouble to write. It is for this reason that the following material in a greatly abbreviated form re-states facts previously presented on the products named.

Pfunder's Stomach Tablets—This was the subject of an article that was published by the Bureau of Investigation in THE JOURNAL, Dec 1, 1928. It was brought out in that article that Frederick H Pfunder of Minneapolis put out what was called "Pfunder's Stomach Tablets a Remedy for Ulcers of the Stomach." A letter had been written to Mr Pfunder in 1926, asking him whether he was willing to give any information regarding the medicinal ingredients of his "patent medicine." He replied that he was willing to give any information "except to reveal the formula"—that is, the only information that the public had a moral right to demand he was unwilling to give. Because of this refusal to throw any light on the composition of his "Remedy for Ulcers of the Stomach," the Bureau of Investigation asked the A M A Chemical Laboratory to analyze Mr Pfunder's nostrum. As a result of their analysis the chemists reported that each daily dose (3 tablets) of the preparation would be equivalent to

Bismuth subnitrate	33 grains
Magnesium oxide	25 grains
Baking soda	27 grains

Uvursin—Uvursin is put out by the John J Fulton Company of San Francisco and is sold as a remedy for diabetes. According to some of the advertising, Uvursin is said to "combine the desirable principles" of chimaphila (pipsissewa), eupatorium (boneset), pareira, taraxacum (dandelion), uva ursi (bearberry), jublans (butternut bark), lappa (burdock root), mulla (elecampane), eriodictyon (yerba santa), zea mays (corn silk), with some senna potassium nitrate and sodium borate. In other words, the product is essentially a mixture of herbs, most of which have long been discarded by scientific medicine and nearly all of which have mild diuretic action. In this respect Uvursin runs true to the orthodox diabetes-cure quackery. Give the diabetic a kidney stimulant so that more urine will be passed, and the patient will be gratified to find that he apparently has a lessened amount of sugar in the urine. The facts are of course, that there is no real diminution in sugar, but because of the increase in fluid output, any individual specimen of urine will naturally have a smaller proportion of sugar in it. Uvursin is apparently the same product that the John J Fulton Company used to put out under the name of "Fulton's Compound B 2." This preparation was declared by the federal authorities to be worthless as a cure for diabetes and the courts held that the implied claim that it would cure diabetes was false and fraudulent. The Fulton concern attempted to evade the federal law by declaring that they themselves did not make the claims for curative effect but that they merely quoted testimonials stating, in effect that it was a cure for diabetes. One federal judge on the Pacific Coast upheld this preposterous thesis, but the Circuit Court of Appeals reversed that judge's decision. The case was then remanded

to another United States District Court and judgment was obtained against the Fulton concern. A somewhat lengthy and detailed article on the Fulton Compound was published by the Bureau of Investigation in *THE JOURNAL*, Jan 29, 1916. In this article case after case was cited of individuals who had given testimonials to the Fulton Company and which that company printed, indicating that the stuff had cured diabetes. It was shown that the patients were dead, having died of the very disease of which they had claimed to be cured. The article has been reprinted in the pamphlet "Nostrums for Kidney Disease and Diabetes" (15c). Since the change of name has been made, the Fulton concern has widely circularized the medical profession.

Renton's Hydrocin Tablets—The Renton Company of Pasadena, Calif., has for some time put out an alleged rheumatism cure for which it used to make the claim "What insulin is doing for diabetes, Renton's Rheumatic Tablets are doing for arthritis, neuritis and rheumatism." At that time the "patent medicine" was known as Renton's Rheumatic Tablets. Apparently pressure brought to bear by the National Food and Drug officials caused them to change the title to Renton's Hydrocin Tablets. Extensive analytical work done by the A M A Chemical Laboratory brought out that the tablets were essentially five-grain cinchophen tablets, with a small amount of what appeared to be tetra-ethyl-ammonium hydroxide. In the Bureau of Investigation's original article on this product, published Jan 17, 1931, attention was called to the fact that the public, in purchasing Renton's Hydrocin Tablets, was paying an exorbitant price for cinchophen and in ignorance of the fact that it was getting cinchophen. Further, it expressed the opinion that it was little less than criminal that irresponsible "patent medicine" exploiters should be permitted to put so potent a drug in secret mixtures with no warning, especially as the number of cases of acute yellow atrophy of the liver following the continued use of cinchophen was increasing. Since the article was published, there have been a number of cases of poisoning reported following the use of the Renton nostrum, including the deaths of six people who had taken the Hydrocin Tablets, and in all of them autopsy disclosed symptoms of cinchophen poisoning.

Viavi—A piece of quackery that has been exploited throughout the United States for many years, known as "Viavi," was the subject of an extended article that appeared many years ago (April, 1907) in the *California State Journal of Medicine*. The Viavi Company is said to have been founded by two brothers, H and H E Law of San Francisco. Viavi is not the name of a single preparation, but a generic name given to a long list of nostrums put out by the Viavi Company. Practically all of the preparations are for the alleged treatment of diseases peculiar to women. There are "Viavi Capsules," "Viavi Cerate," "Viavi Liquid," etc. So far as analyses have been made of them, the basis of most of the Viavi preparations seems to be extract of hydrastis (golden seal). The method of sale of the Viavi preparations is not that of the usual "patent medicine." They are not handled by druggists and they are apparently not sold on the mail-order plan. The business seems to be carried on by means of agents. However, there has been one reported case of misbranding under the National Food and Drugs Act, that described in Notice of Judgment No 19466, issued December, 1932. Viavi Liquid and Viavi Cerate were both included in this prosecution, which was based on the fact that the therapeutic claims were false and fraudulent. One of the methods that have been reported as used by Viavi representatives in order to make "contacts" was that of getting well-meaning church women and unsophisticated parsons to act as pawns in the game of quackery. Cards would be sent out by the Ladies Aid Society of a given church, inviting women to attend an illustrated talk on the "Science of True Living," to be given "under the auspices of the Educational Department" of some branch of the Viavi concern. The bait was the promise that the Viavi agent would pay the Ladies Aid Society 10 cents for every woman who attended the "lecture." What the Viavi business sometimes does was well described in a brief article that was published in *THE JOURNAL*, Dec 3, 1927. A well-known physician in the middle west reported at that time that he had been called to see a twenty-

seven-year-old woman whom he had known for many years, as he had been the attending physician of the family. He was called suddenly because the woman had a severe uterine hemorrhage. On examination he found unmistakable evidence of cervical carcinoma of several months' standing. He was told that the young woman some four months previously had begun to lose weight, had severe pelvic pains, discharge, etc., and her husband had told her to go to the family physician. A neighbor, however, advised her to see the local Viavi agent first, which she did. From the agent she got two bottles of Viavi, one costing \$9.50 and the other \$3.50. The Viavi agent sent the woman's "symptom blank" to the Viavi branch headquarters, and the mail-order diagnosis was made that the condition was probably a "cyst" which would require several months' Viavi treatment to absorb. As the family physician wrote "Four months ago there might have been a chance to save the life of this young mother, today the case is practically hopeless."

R M B Prescription—This preparation, put out by the so-called R M B Laboratories of Seattle, Wash., used to be sold under the name "Asthma-Sera" and was advertised under the claim that it "ends asthma and hay fever forever." The Bureau of Investigation published an article on the subject in *THE JOURNAL* of Feb 11, 1928. The product was found to have the composition that nine out of ten "patent medicines" for asthma do have, namely, iodides. The A M A Chemical Laboratory, which analyzed the stuff under its earlier name at the request of the Bureau of Investigation, reported that the daily dose of the nostrum (4 teaspoonfuls) had the equivalent of 236 grains of strontium iodide, 116 grains of sodium iodide, and a laxative. This commonplace mixture was sold under the claim that it was a new treatment discovered by a French physician and never before used in either Canada or the United States in the combination found.

Free Breath—This preparation, sold as an alleged treatment for asthma and hay fever, is put out by the O W Dean Company of Benton Harbor, Mich., which had earlier been known as the Benton Asthma Remedy Company. Free Breath was described as the "World's Wonder Treatment for Asthma, Bronchitis, Hay Fever, and Catarrh of the Mucous Membranes." O W Dean, president of the company, was, if he is not still, an undertaker. The details of this piece of mail order quackery were set forth in an article published by the Bureau of Investigation in *THE JOURNAL*, Nov 27, 1926. At that time Free Breath was a liquid. It is now apparently sold in solid form, which should allow greater profits because of the lessened shipping costs. Free Breath was analyzed by the A M A Chemical Laboratory, which reported that the stuff contained the equivalent approximately of 21 grains of potassium iodide and 24 minims of solution of potassium arsenite (Fowler's solution) to the fluid ounce. This would mean that each dose was equivalent to $2\frac{1}{2}$ grains of potassium iodide and 3 drops of Fowler's solution.

Renesol—Renesol was one of several names used by Charles Goldblatt and Maurice E. Goldberg, who sold phenobarbital (luminal) at an exorbitant price as cures for epilepsy. The Goldblatt-Goldberg combination operated such mail-order fakes as the Renesol Laboratories, Inc., the Nurosol Laboratories, Inc., the Nurone Laboratories, Inc., the Vitosol Corporation and the Phenoleptol Company, all putting out "patent medicines" for the alleged treatment of epilepsy and all of them essentially phenobarbital. An extended article on this variously named piece of quackery was published by the Bureau of Investigation in *THE JOURNAL*, Feb 20, 1932. The analysis made by the A M A Chemical Laboratory disclosed that each capsule of Renesol contained approximately one grain of phenobarbital, to which had been added a small quantity of baking soda.

Haines' Golden Treatment—This is one of those cruel humbugs exploited as a cure for the liquor habit. It was the subject of an article by the Bureau of Investigation in *THE JOURNAL* Oct 27, 1917. It was brought out in that article that prior to the passage of the present Food and Drugs Act, when lying on the trade package was only immoral instead of expensive the stuff was labeled "Golden Specific." The preparation

is one of the numerous fakes exploited as cures for alcoholism which can be given secretly, curing the alcoholic in spite of himself. Not only is the claim that the stuff can be administered and will cure the drunkard "without his knowledge" false, but it is a viciously cowardly falsehood, in that it deceives those who, in the very nature of the case, are not in a position to protest when the deception becomes obvious. An analysis made in the A M A Chemical Laboratory was also part of the article already referred to. It was declared that Haines' Golden Treatment was composed essentially of milk sugar, starch, red pepper, and a minute amount of ipecac!

Frontier Asthma Remedy—This is a mail-order concern that is apparently conducted by one George H. Calkins, M.D., who also seems to have as a side-line an alleged mail-order remedy for piles. A brief note on the Frontier Asthma Remedy was published in *Hygeia* for June, 1929, in an article "Hay-Fever and Asthma Quackery." The claim is made for the Frontier remedy that individual treatment is given to the mail-order patients. While there is reason to believe that there may be some variations in the composition of the mixtures sent out to different persons, the essential ingredient seems to be iodides. Every analysis of which we have record shows the presence of these drugs. An analysis made by the A M A Chemical Laboratory in 1916 showed that each dose of the Frontier nostrum examined contained the equivalent of about 5 grains of potassium iodide, together with $\frac{3}{4}$ of a grain of caffeine and $\frac{1}{60}$ of a grain of arsenous oxide. In four analyses reported by the Chemical Laboratory of the City of Cleveland in 1919, all specimens were found to contain iodides. The state chemists of Connecticut, in a report issued in May, 1927, stated that a sample of the Frontier remedy, when analyzed, was found to contain iodides, ammonia and caffeine. In other words, the Frontier product, like nine-tenths of the nostrums sold either as "patent medicines" through the retail trade or as mail-order remedies for asthma and hay fever depends for its action on the iodides, whose value—and limitations—in the treatment of certain forms of asthma have been known for years.

Midol—This "patent medicine" has been advertised for some time as a "pain killer" for use at the time of the menstrual periods. In the past emphasis has been laid on the danger of taking acetanilid or acetphenetidin, and the public is assured that Midol contains neither of these substances. Midol was analyzed in the A M A Chemical Laboratory in 1912. At that time the chemists reported that a Midol tablet averaged about $6\frac{1}{2}$ grains, of which a little less than $\frac{1}{2}$ of a grain was talc, about 1 gram starch, and the balance of the tablet mainly amidopyrine with a small amount of caffeine. It was concluded that Midol depends for whatever therapeutic action it has essentially on the amidopyrine. The increasing evidence of a possible relationship between the continued use of amidopyrine and the production of granulopenia, emphasizes the danger of the indiscriminate use of "patent medicines" containing amidopyrine.

Crazy Crystals—This product has been claimed to be the mineral constituents that are obtained by evaporating a water known as 'Crazy Mineral Water.' The product Crazy Mineral Water has been on the market for many years and has been declared misbranded (because of fraudulent curative claims) or adulterated (because it contained filth) at different times in the past. The exploiters of Crazy Mineral Water have published what purported to be the ingredients of the water, and while they have varied, they all agree in showing that the chief mineral ingredient is sodium sulphate (Glauber's salt). Crazy Crystals was the subject of an article by the Bureau of Investigation published in *THE JOURNAL* of March 11, 1933. It was there declared in summing up the matter, that a \$1.50 package of Crazy Crystals could accomplish nothing that could not be accomplished equally well with a few cents worth of Glauber's salt. It was further stated that the attempt in the radio advertising of Crazy Crystals to lead the public to believe that the preparation was not a drug was but playing tricks with the English language for Crazy Crystals is just as much a drug as Glauber's salt or any other saline laxative sold for the treatment of human ailments.

Correspondence

"DERMAL MANIFESTATIONS OF VITAMIN A DEFICIENCY"

To the Editor—I have read with interest the editorial on "Dermal Manifestations of Vitamin A Deficiency," which appeared in *THE JOURNAL*, March 10. In connection with this I should like to refer you to an article by myself and Dr. C. K. Hu on "Cutaneous Lesions Associated with a Deficiency of Vitamin A in Man" which was published in the *Archives of Internal Medicine* 49:507 (Sept.) 1931. I think you will find that Dr. Loewenthal's observations in general are similar to those made in Peiping.

Peiping Union Medical College,
Peiping, China

SUPRARENALECTOMY IN ESSENTIAL HYPERTENSION

To the Editor—In *THE JOURNAL*, April 7, page 1118, the results of suprarenalectomy in essential hypertension are reported. It seems to me that the therapeutic importance of this paper is lost by the failure of the authors to control adequately their studies of the blood pressure. Thus, patient 1 entered their clinic apparently for the first time, Oct. 7, 1933, and on October 17, after ten days' observation, was operated on. Such a brief period of observation is of little value in determining the effect of subsequent therapy. Weeks and even months of careful observation under standard conditions are needed in any study of essential hypertension. The truth of this statement is illustrated by the following case.

M. R., aged 55, was first seen with a blood pressure of 240 systolic, 130 diastolic, which dropped at the end of twenty minutes' rest in a chair to 190 systolic, 120 diastolic. The patient was seen at weekly intervals, during which time no medication was given. The drop in blood pressure that occurred during these weeks of observation without treatment is indicated in the accompanying table.

Date	Initial Blood Pressure	After 10 Minutes Rest	After 20 Minutes Rest
9 2 33	240/130	210/120	190/120
9 9 33	208/120	180/110	194/120
9 16 33	180/110	160/94	150/94
9 23 33	184/108	164/98	160/100
9 30 33	200/110	164/108	160/100
10 7 33	170/98	158/90	152/90

Such an example is the rule rather than the exception, when a hypertensive patient is seen for the first time in the office or clinic.

DAVID AYMAN, M.D., Boston

[NOTE—The letter was referred to Dr. Joseph L. DeCourcy, who writes.]

To the Editor—Let me advise that it has been the policy of my associates and myself to have these patients under observation in the hospital for one week before operating. This was done with patient 1 and three hourly readings were made. During this time the diastolic pressure did not go below 140.

To date we have operated only in the so-called malignant type of hypertensive case and it has been our experience that, though the systolic pressure varies considerably, the diastolic does not go below 130 or 140 even with rest in bed.

It is also a fact that patient 1, as stated in the original article, had been in bed two months before operation and during this time the diastolic pressure did not go below 140.

We feel confident that our results will improve if we can operate on these patients early, before vascular changes have taken place

At present we are trying to determine the effect of sclerosis present by examination of the eyeground and will make a detailed report later

JOSEPH L. DECOURCY, M.D., Cincinnati

Queries and Minor Notes

ANONYMOUS COMMUNICATIONS and queries on postal cards will not be noticed. Every letter must contain the writer's name and address but these will be omitted, on request

INHALATION OF OXYGEN IN PNEUMONIA

To the Editor—In Queries and Minor Notes in THE JOURNAL, January 27, page 311 there was consideration of the treatment of pneumonia at home. Reference was made to the use of oxygen by the use of a catheter placed in the nostril. Just how these arrangements are to be carried out and the details of the valves and other mechanism are a bit hard to figure out. Can you direct me to some information that will be able to enlighten me? Some manufacturer of such apparatus would be able to explain the details but I do not know of any or the address. Should you happen to know of any one using this form of oxygen medication I shall be glad to get his name and address

Mont

ANSWER—An increase in the concentration of oxygen in the upper air passages, and consequently in the lungs, may be accomplished by leading oxygen into the nares by means of a

Fig 1—The method of using oxygen with a Bullowa catheter in an adult. The Air Reduction Company's variable orifice meter and flow back bottle

catheter. Two types of catheter are employed (1) metal catheters, which may have rubber tips or extensions, and (2) soft rubber tubing. Rubber catheters have been effectively employed by Barach, Barker, Waters and others and can be obtained in any reliable surgical supply house. Metal catheters are usually Y-tubes, shaped so as to fit just inside the nostrils. They should be made of malleable brass so as to permit bending. Several catheters of different kinds should be at hand because of the variation in facial contours. The Bullowa type, with band plate adjustable on the stem, is made by Frederick L. Noble of 2136 Seventh Avenue, New York City. The Connel and the Sanford types are made by the Foregger Company, Inc., 55 West Forty-Second Street, New York City.

Soft catheters may be attached to the bulbous ends of the metal catheter or to a glass tube connected with the oxygen supply. The ordinary urethral catheter No. 10, French, may be employed, provided holes are cut or punched at intervals of one-half inch so as to prevent a localized blast of air. The soft rubber tube or tubes may be introduced 1½ inches and either rest on the floor of nose or extend to the oropharynx,

in that case the length may be determined as the distance from the plane of the upper lip to the external auditory meatus. The catheters are kept in place with a band about the head or with an adhesive strip.

If dry oxygen were admitted to the nostrils, the mucous membranes would be dried and soon would become congested

Fig 2—The soft rubber catheter in a child

and ultimately inflamed, and the patient would reject the treatment. Accordingly, the oxygen is passed through several inches of water in a wash bottle. The Burdick oxygen humidifier manufactured by the Burdick Corporation of Milton, Wis.,

Fig 3—A the Bullowa catheter B soft rubber catheter with perforations C the Connel catheter with soft rubber tips

appears to be a satisfactory instrument for this purpose. An oxygen flow rate of 4 liters per minute for adults and from 15 to 2 liters per minute for children, has proved satisfactory and will give a pharyngeal oxygen of about 27 per cent, or a 50 per cent increase in the concentration usually found in the pharynx.

Regulators for the clinical delivery of oxygen are made by a number of manufacturers and may be obtained from local dealers in industrial oxygen or from the surgical instrument dealers (There is no medical oxygen. The oxygen used in garages for welding is suitable for inhalation and may be purchased from dealers in industrial gases.) The clinical regulators have the delivery gages graduated in liters. A two-stage regulator is desirable because it requires less observation to maintain a constant flow, permits more complete emptying of the oxygen tank, and protects Bourdon tube gages from excessive and sudden pressures.

There are two types of gages

1 The variable orifice or float gage in which a weight is supported by the flowing gas in a funnel shaped tube. The orifice between wall and weight varies, increasing in the upper portion of the tube. The number of liters flowing when the weight is supported at any given height is indicated on the tube. Should the outlet be obstructed so that less gas is escaping, the weight will fall and the amount flowing will be correctly indicated. The Air Reduction Company, 60 East Forty-Second Street, New York City makes such a gage.

2 The fixed orifice gage (Venturi principle). The amount of gas escaping through a given sized orifice is dependent on the pressure of the gas, so that a pressure gage may be calibrated in liters per minute to indicate the flow. If the flow of gas is free these gages may be accurate, but if the flow is obstructed the gage will indicate the same or a higher flow rate than is actually flowing. Sometimes the capillary opening becomes obstructed and this will impede the flow of oxygen and require a change in the calibration. The Bourdon tube may be sprung by sudden, excessive pressure, especially in one-stage regulators. The ordinary dial gages contain Bourdon tubes, these are curved tubes of metal which straighten when the pressure increases within them. By means of a ratchet attached to the end of the tube, the indicator on the dial is moved.

A recent production of the Linde Air Products Company is the Linde oxygen therapy regulator, type R-51, which has two stages of expansion and has been accepted by the Council on Physical Therapy of the American Medical Association.

In order to avoid breakage of the regulators, the tanks of oxygen should be strapped to the bed post so that delirious patients or persons moving about may not overturn them.

TREATMENT OF CERVICITIS

To the Editor—Kindly state what treatment could be applied in a case of chronic cervicitis the patient having a yellow watery copious discharge of foul odor of three years duration. The patient is single 26 years of age a bookkeeper and of nice reputation. She had a cervical cauterization (electrical apparently) about a year ago with no alleviation of the leukorrhea. She has had numerous treatments by various doctors and she is quite hopeless as to cure as far as she is concerned.

AARON I LEVIS M.D. Madison N.Y.

ANSWER—From the description given it is almost certain that this patient's annoying discharge is not due to a cervicitis, even though the latter may still be present but to trichomonas vaginalis. This belief is supported by the clinical symptoms enumerated and the persistence of the discharge in spite of various forms of treatment. Most likely the patient may be treated just as any married woman because with all the manipulation she has had the hymen has undoubtedly been ruptured and the vagina stretched.

In order to make a diagnosis of *Trichomonas vaginalis*, it is necessary to examine a fresh unstained drop of the discharge, diluted with a drop of physiologic solution of sodium chloride. *Trichomonas* is an actively moving paramecium-like organism and easy to detect.

There are many ways of treating a discharge due to this organism, and almost all types of drugs have been used. Thus far no specific has been found, but immediate relief can be given in most cases with almost any type of treatment though recurrences are frequent. The treatment outlined by Greenhill (THE JOURNAL May 30 1931 p 1862) is as follows.

The vagina is thoroughly scrubbed with gauze or cotton saturated with tincture of green soap (liniment of soft soap U.S.P.). All the vaginal folds are smoothed out and every part of the mucosa is scrubbed. The scrubbing is one of the most important steps in the treatment, and it is usually persisted in until slight bleeding is noted in the vaginal mucosa. Bleeding generally occurs because the mucosa in these cases is friable. The soap is washed out with tap water or with mercuric chloride and the vagina is dried thoroughly. A speculum is inserted into the vagina and hexylresorcinol solution (1:1,000) is instilled into the vagina and on the cervix.

A tampon saturated with half or full strength glycerin is then inserted high up into the vaginal vault. A second, dry, tampon is inserted to prevent the escape of glycerin on the patient's clothing. Hexylresorcinol solution (1:1,000) is applied to the vulvar and anal regions and the patient is instructed to remove the tampons after twenty-four hours. The string of the second tampon has a knot tied in it, so that the patient may know that this tampon is to be pulled out first. After removal of the tampons, a douche of tincture of green soap is taken. The treatment outlined is repeated every second day for at least three times. The patient takes a green soap douche on the mornings between treatments but not on the mornings she is to receive a treatment. A douche is not taken on the morning of a treatment because it is desirable to see how much discharge there is and also because hanging drop examinations are made at that time. Treatment is continued until hanging drops on two successive visits fail to show *Trichomonas*. However the patient is advised to take a 0.5 per cent lactic acid douche daily for about two weeks after treatment is discontinued. The purpose of the lactic acid douche is to attempt the reestablishment of a normal bacterial flora in the vagina.

A matter of great importance is the cleansing of the anus after a bowel movement. To accomplish the latter most women use an upward sweep toward the vagina and urethra, but this may produce reinfection if the causative organisms come from the rectum. The patients are instructed to use a sweeping motion directed away from the vagina and toward the sacrum. The significance of this method of cleansing the anal region should be impressed on the patient.

Since recurrences of the troublesome discharge occur in a certain proportion of cases, and since these frequently manifest themselves immediately after a menstrual period it is advisable to reexamine patients just before and just after a menstrual period. If organisms are found, a course of treatments should again be given.

TECHNIC OF MANTOUX TUBERCULIN TEST

To the Editor—The Mantoux test is being given in the schools at the present time (0.1 mg.) and the following questions have arisen: 1 Will 0.1 mg. light up a childhood type? 2 Will 0.1 mg. light up an adult type otherwise quiescent? 3 Are there any contraindications for the tests in children excepting the adult type? 4 What are the contraindications in an adult? Please omit name.

M.D. Ohio

ANSWER—One-tenth milligram of old tuberculin has been administered intracutaneously as the initial dose in diagnostic work by a large number of physicians. Many of them still use this amount as the initial dose in tuberculin testing of both children and adults. If the individual tested is highly allergic, a four plus local reaction may result that is a small area of necrosis is produced. This is not serious in any way and occurs so rarely that 0.1 mg. may be considered a safe dose from the standpoint of the local reaction. However, some physicians prefer to use as the initial dose only 0.01 mg., since with this amount one almost never sees a four plus reaction. With 0.1 mg. of tuberculin properly introduced into the layers of the skin there is no constitutional reaction. The tuberculin is absorbed very slowly and is present in such a small amount that it does not light up the childhood type of tuberculosis, nor is there any evidence to show that it lights up an adult type of tuberculosis otherwise quiescent. In children with the adult type of tuberculosis the intracutaneous tuberculin test is not contraindicated nor is it contraindicated in adults with the adult type of disease.

Apparently a great many physicians have confused the intracutaneous test with the subcutaneous test which was extensively used for a time but which often did result in constitutional symptoms, such as elevation of temperature, acceleration of pulse and malaise. Moreover, it sometimes resulted in focal reactions, that is around the site of the tuberculous focus in a lung there would appear increased shadow on the x-ray film, probably because of collateral inflammation. On auscultation one would occasionally find increase in rales. In patients with tuberculous cervical lymph nodes, large doses of tuberculin administered subcutaneously would result in increased enlargement and even tenderness over the nodes. There is little doubt that tuberculous lesions were sometimes lighted up by subcutaneous administration of tuberculin, owing to the large dose and the rapid absorption. However, from the small dose and the slow absorption by the intracutaneous method one need fear no danger. The occasional coincidence has led some physicians to fear the intracutaneous test. For example, The person who has had the test administered may within a few hours to a day or so develop symptoms, such as elevation of temperature due to an acute respiratory infection but for which the tuberculin was in no way responsible.

PARALDEHYDE IN RECTAL ANESTHESIA

To the Editor—In the article on "The Role of Pharmacology in the Development of Ideal Anesthesia" by C. D. Leake (*THE JOURNAL*, January 6), the statement is made that paraldehyde is satisfactory for rectal narcosis in place of tribromethanol. Reference was made to Stewart J. D. Rectal Paraldehyde Before Operation, *Brit. M. J.* 2, 1139 (Dec. 24) 1932. Would you give me the technique and dose used according to age and weight? Please omit name and address.

M D, Oregon

ANSWER—Stewart's report, to which reference was made, was based on experience with 500 cases. The patient was given an enema the evening before the operation, and barbitol by mouth as a sedative. The next morning an hour and a half before the operation, 0.7 mg ($\frac{1}{400}$ grain) of atropine sulphate was administered hypodermically (no morphine), and this was followed by the rectal administration of freshly prepared paraldehyde solution. The latter was approximately 10 per cent in physiologic solution of sodium chloride, which was found to be retained without difficulty if the rectal administration was slow. The adult dose was 8 drachms (32 cc.) of paraldehyde for patients weighing more than 8 stones (112 pounds, or 50 Kg). For patients under this weight the dose was in the proportion of 1 drachm of paraldehyde per stone, which is equivalent to 1 cc of paraldehyde for 18 Kg.

Another report on paraldehyde used rectally for basal narcosis was made by J. L. Thompson and L. J. T. Hartnett (*M. J. Australia* 2, 682 [Dec. 3] 1932). Their report was based on experience with seventy cases in which the dosage of paraldehyde was from 0.3 to 1.2 cc per kilogram in five times that amount of physiologic solution of sodium chloride administered rectally half an hour after a hypodermic injection of morphine, atropine and scopolamine, and one hour before the operation. These authors found that sleep occurred by the end of such administration, that anesthetization was simple, and that much less anesthetic agent was required than otherwise. Although unconsciousness was maintained several hours after operation, the reflexes returned quickly when the actual anesthetic was stopped. No unpleasant odor or taste was noted by any of the patients. Paraldehyde is recommended because it lessens the shock and postoperative pain, is easy to administer, is safe and certain in action, and is inexpensive.

PAINFUL FEET

To the Editor—Why is it that certain people employed in mercantile establishments and constantly walking about on a hard floor surface without any demonstrable physical or roentgen changes in either foot, complain of considerable pain during their hours of employment? The pain exists in both feet involving the metatarsophalangeal area, and is relieved when the patient operates a delivery truck or walks on other than a hard surface, in spite of the latter not being of even contour in fact being rough. The patient in mind is 23 years of age and has purchased every type of shoe and support for the foot but cannot get relief. This condition has existed for several years and of late is becoming quite a problem. Can you give me an explanation of what the condition is called, the prognosis and the treatment? Please omit name.

M D, Wyoming

ANSWER—The condition described would be classed as metatarsalgia, or foot strain.

The muscles are the first line of defense. After they have been strained to the limit, ligamentous strain comes into the picture. Standing is usually worse than walking, because in walking the muscles are used only intermittently.

In driving a truck the man exercises his muscles, especially the interossei, and keeps all other muscles and ligaments in good tone. Some of these patients develop "march foot" with an actual fracture.

USES OF EPSOM SALT COMPRESSES

To the Editor—I find many doctors using hot epsom salt compresses to localize infections such as abscesses. What does the work, the epsom salt or the heat? Would dry heat or infra red be just as efficient? Is there any special virtue to hot epsom salt compresses in infection after an incision has been made? Does the hypertonic solution actually "draw out the purulent material"? If so is there any preferable concentration of epsom salt? Is epsom salt solution antiseptic in any degree? Please omit name.

M D, Texas

ANSWER—Moist heat is often more soothing than dry heat, such as the infra-red. Warmth dilates the vasomotor nerves, producing a better blood supply, which aids tissue defense against infection and repair after injury. Where tension is present, heat may aggravate the pain and be contraindicated. A warm saturated solution of magnesium sulphate (epsom salt) applied to the skin exerts a soothing action in local inflammation whether from injury or infection, although as observed in erysipelas there may be no checking of the infection. An actual beneficial as well as soothing effect has been

proved after burns of the skin. Magnesium sulphate has also been found to be of great service in the treatment of infected wounds when applied as a paste. A paste of 765 Gm of dried magnesium sulphate and 350 Gm of glycerite of phenol has been found satisfactory in packing infected wounds. The injection of magnesium sulphate causes an increase in phagocytosis but no leukocytosis. Experimentally there is no migration of leukocytes from the application of magnesium to the frog's mesentery. It has no anesthetic effect on mucous membranes but does have a selective action on the motor endings of nerves, even in small doses. Solutions from 12.5 per cent to a saturated solution have been found to be soothing, to increase phagocytosis and to favor tissue repair.

EPILEPSY

To the Editor—A woman, aged 36 developed epilepsy at the age of 24 years. She has been having grand mal attacks occasionally in spite of medication, and two weeks ago she had several attacks in one night, followed by a delirium in which there have been no hallucinations but delusions. She has been rather excited and it has been necessary to use a chloral and bromide mixture and sodium amylal. This was interpreted as a status epilepticus equivalent and as such it should be expected to last only a week or two. She has had experiences somewhat similar to this lasting a week, however this is going on to the third week and there has been no change other than transient moments of more normal personality. Physical examination is negative with the exception that she has had an operation for removal of both tubes, ovaries and the uterus. I should be interested to have your comment about this condition if possible from this limited information. Please omit name.

M D, Michigan

ANSWER—Whenever convulsions begin after the age of 21, the diagnosis of idiopathic epilepsy should be held in reserve. It would be important to know whether this patient had any convulsions in childhood which might be considered the onset of the disease. The majority of epileptic patients have their first convulsions some time before puberty. In this case it would be advisable to obtain a careful history as to epilepsy in the family and then to make an extremely careful examination of the patient. This should include an examination of the optic fundi, a roentgenogram of the skull, a Wassermann test on both blood and spinal fluid, and an examination of the spinal fluid. If an organic lesion and syphilis can be definitely excluded, the diagnosis of epilepsy might be considered. A frontal lobe tumor, cerebrospinal syphilis and encephalitis must be considered in the diagnosis. The delirium and delusions might be caused by the medication. Bromides may eventually produce a mental deterioration, and phenobarbital may in some cases produce symptoms similar to intoxication with alcohol. If the examinations reveal no further information, it would be advisable to attempt to control the patient's condition with deodorized tincture of opium, which will produce cerebral sedation. Subsequently one of the barbiturates, preferably phenobarbital, may be administered in increasing dosage until the seizures are under control.

PROTECTIVE SUBSTANCES FOR SKIN

To the Editor—A cobbler consulted me about the condition of the skin on his thumb and first two fingers of his left hand. The skin is dry, thickened and scaly and at times it cracks open and bleeds. The fingers are very painful and he keeps them protected with gauze, which naturally interferes with his work. The index finger and thumb which he uses to pick up and hold shoe nails are the worst. This condition has existed for several years and he has tried many preparations to relieve the condition but without success. Can you tell me anything that might give this man relief?

H. H. Ash, M.D., West Lafayette, Ind.

ANSWER—The shoemaker and repairer is exposed to many irritants, such as those used in the complicated processing of leather, those present in shoe dyes and polishes, and the wax he uses in sewing leather. It is no wonder that dermatitis of the fingers is a common affliction. Attempts to soothe and heal the skin are unavailing because of repeated exposure. An attempt may be made to discover which of the many irritants is responsible. Patch tests are made by applying a small amount of the substance to be tested to apparently normal skin, covering it with gutta percha, rubber dam or oiled silk, and fastening this on with adhesive tape. If no itching is felt the patch may be left on for two days. At the end of this time, or earlier if itching is felt, it is removed and the reaction read. Any dermatitis at the center is recorded as positive.

If the substance found responsible for the dermatitis can be avoided, the difficulty is solved. If, however, it is indispensable in the work, he may be able to protect his skin by coating his hands with a protective dressing not thick enough to hinder the action of the fingers but sufficient for protection against any but watery solutions. After washing it must be renewed.

After work, it is washed off and a soothing ointment applied. If the skin is found sensitive to alkalis (a test with soap solution should always be included among the patch tests), plain water, oatmeal water, ointment of rose water or liquid petrolatum may be used for washing.

POLLENS IN NEW YORK AREA

To the Editor—A boy aged 5 years, contracted hay fever the second day of last August which lasted through to the early part of September. His parents are considering sending him to a camp in the Schroon Lake area in upper New York State with the hope of avoiding a recurrence. 1 Is this botanic area suitable? 2 Is there any better place within a radius of 300 or 400 miles from New York City? Please omit name.

M D, New York

ANSWER—It is assumed that this boy is sensitive to ragweed, although the history is not quite typical, the symptoms beginning and terminating rather early.

1 No local pollen surveys have been reported for the Adirondack region, but because of the predominance of forest flora there is reason to believe that there is less ragweed pollen in the vicinity of Schroon Lake than in the surrounding populous areas where atmospheric studies have been made. The approximate average annual fall of ragweed pollen in surrounding districts is as follows:

New York 1606 pollen granules to 18 sq cm or 100 pounds per square mile.

Buffalo 8,992 pollen granules to 18 sq cm or 563 pounds per square mile.

Montreal 744 pollen granules to 18 sq cm or 47 pounds per square mile.

Boston 790 pollen granules to 18 sq cm or 50 pounds per square mile.

2 There is no place within 400 miles of New York City which has been proved by atmospheric tests to be free from ragweed pollen. Two localities, however, enjoy considerable popularity and are probably relatively free. These are Bethlehem, N H, in the White Mountains, and the Georgian Bay region of Ontario. It is likely that either of these places would be better than the Adirondacks, since they are farther from agricultural areas and less likely to be affected by ragweed pollen blown in on prevailing westerly winds.

PREMATURE INFANTS

To the Editor—Just what constitutes a premature infant? Would a 5 pound infant born at what is believed to be term from an apparently healthy mother be called premature? Davis asks 'Is it customary to designate as premature all infants who at birth weigh between 1500 and 2500 Gm?' and states that 'immature as here used is the expression applied to any infant weighing less than five pounds.'

J D WALLER M D Wilmont Minn

ANSWER—Ordinarily an infant born before the fortieth week of intra-uterine life is considered to be prematurely born. However, many infants born from one to three weeks before term are so well developed that they are treated much the same as a full term infant. An infant weighing 5 pounds (2268 Gm) might be a premature infant, an immature full term infant, or a small full term infant commonly seen in twins. The decision as to how to treat this child would depend largely on its physical condition and the state of its development as manifested by its skin and nails, and its ability to maintain a normal temperature and digest food mixtures ordinarily taken by a new-born infant.

FUSIFORM BACILLI IN MOUTH AND VINCENT'S ANGINA

To the Editor—In the course of many examinations of patients gums and throats for the organisms of Vincent's angina I have frequently found smears that contained both fusiform bacilli and Spirochaeta refringens without there being any lesions definitely demonstrable. I should like to have some information as to the incidence of positive smears in the absence of any well marked lesions and also the extent to which the disorder is communicable in situations such as this. What treatment would you recommend for cases of this kind?

ROSS McC CHAPMAN, Towson Md

ANSWER—There is a marked difference of opinion both as to the facts and as to their significance with reference to this question. Smith (Oral Spirochetes Baltimore, 1932, p 68) says 'Fusiform bacilli, spirochetes, vibrios and cocci are normal inhabitants of the mouth. A few of these organisms are always to be found in smears from the gingival groove. Under conditions of disease they are enormously increased in number.' Appleton (Bacterial Infection Philadelphia, 1925, p 409) is of the opinion that 'Healing of the lesions goes on parallel with the disappearance of the organisms. When complete no organisms remain. However it must be admitted that the weight of opinion supports the belief that these bacteria

are common in filthy mouths and in persons with unhealthy gums, as in pyorrhea. Treatment in such cases should be directed to the elimination of conditions that favor multiplication of these organisms, such as gingival flaps over partly erupted lower third molars, dental defects favoring the collection of food or other debris, calculus, dental decay and diseased tonsils. It is possible that the carrier may be concerned in transmitting this disease, but there is no evidence to support such a belief. It would seem much more likely that only the "enormously increased number" in the active stages of the process favor contagion. Therefore only active preventive measures are warranted in dealing with the acute condition.

KERATITIS FROM TYPE WASH

To the Editor—A certain type wash containing either alcohol and phenol (carbolic acid) proportions unknown was accidentally rubbed in the eye of a patient. No immediate pain was noted. The eye became red and a sensation of a foreign body in the eye was complained of. I saw the patient three weeks afterward and found a keratitis profunda but no evidence of ulceration. Could such type wash as used in printing establishments be etiologically connected with the deep corneal inflammation? Is there any available literature on this subject? Please omit name.

M D, Illinois

ANSWER—Yes. Any one of the three substances mentioned could result in the deep keratitis spoken of. A complete digest of the literature to date upon this subject is contained in the following references:

Wagenmann in Graefe Saemisch Handbuch der gesamten Augenheilkunde ed 11 9 1579 1910
Cramer in Kurzes Handbuch der Ophtalmologie 4 528 1931
Wurde mann H V Injuries of the Eye ed 2 St Louis C V Mosby Company, 1932 p 413

PSEUDOHEMOPHILIA HEPATICA

To the Editor—A man, aged 40 known to be an alcoholic addict died suddenly without medical attention. There was a history of marked albuminuria and attacks resembling epilepsy. At necropsy he was found to have chronic nephritis, marked edema and atrophy of the brain and an acutely dilated heart. An unusual finding was the failure of the blood to clot. It had not been hemolyzed. There was no evidence of carbon monoxide, potassium cyanide, strychnine or other poisons. Can you tell me other possible causes of failure of the blood to clot? Please omit name.

M D Iowa

ANSWER—The most likely possibility in an alcoholic addict with this history and no previous evidence of a hemorrhagic diathesis is pseudohemophilia hepatica. The liver is the principal source of fibrinogen formation. Experimental injury to this organ results in a reduction of blood fibrinogen and prolongation of the normal clotting time. Clinically, the prolongation of the clotting time has been observed in persons with cirrhosis of the liver from chronic alcoholism, phosphorus and chloroform poisoning. Frank coined the term pseudohemophilia hepatica for this group of cases.

EXCISION OF HEMANGIOMA

To the Editor—Is surgical excision of a wine colored hemangioma about the size of 7 nickel and slowly growing an accepted method of treatment? It is elevated about one sixteenth inch. The patient is a 3 months old baby girl. The hemangioma is on the abdomen. Kindly omit name.

M D Long Island

ANSWER—Excision of small hemangiomas is an accepted method of treatment. If there is no underlying cavernous angioma, it ought not to give trouble. The excision must be wide of the tumor and care must be taken to ligate the vessels leading to the tumor. The excellent cosmetic results from treatment with the filtered rays of radium have made this a much more popular method at the present time.

PSORIASIS AND CLIMATE

To the Editor—Have you on file any accurate and reliable information as to whether psoriasis is more prevalent in any particular country in the world? Have you on the other hand any information regarding the fact that psoriasis is not seen in Siam? Is it true that psoriasis is rarely seen in countries located on the equator?

ALBERT M CRANCE, M D, Geneva N Y

ANSWER—Psoriasis seems to be more prevalent in the colder climates. Even in the temperate zone the disease is much more common in winter than in summer. It is true that one occasionally will get what is spoken of as an 'inverse' type of psoriasis, whereupon it is worse in summer than in winter. These cases are far in the minority, however.

We have no information as to the frequency of psoriasis in Siam. Probably the same conditions would apply to Siam,

however, as to any tropical country. The disease is not as frequent in the tropics as in the temperate zone. This is due, in part, to the temperature and, in part, to the influence of the sun's rays. It is well known that psoriasis does not appear on the parts exposed to the sun. Moreover, one of the best treatments that dermatologists have for obstinate cases of psoriasis is to send the patient South. Frequently sunning for a few weeks in a warm climate will take care of a very resistant type of the disease, even when it has reached the point at which it seems that nothing will help it.

ANILINE POISONING

To the Editor—Kindly let me know whether there are reports of systemic disturbance of people working in aniline oil.

E. M. FREMAN, M.D., Canton, Ohio

ANSWER—Yes. In every year since 1913, when the first extensive account of aniline poisoning in this country was published, one or more reports have appeared descriptive of this occupational disease. Among others:

Davis P. A. J. *Indust. Hyg.* 3:57 (June) 1921.

Lintz William. *Aniline Poisoning*. *THE JOURNAL* March 3, 1917, p. 692.

Luce R. V. and Hamilton Alice. *Industrial Aniline Poisoning in the United States*. *THE JOURNAL* May 6, 1916, p. 1441.

International Labour Office. *Encyclopedia of Industrial Hygiene*, vol. 1.

DRUGS TO CONTROL REACTION OF URINE

To the Editor—Is there any medication that may be administered by mouth that has a physiologic action of a sedative to the mucous membrane of the posterior urethra and base of the bladder for those conditions of urinary frequency not due to bacterial invasion, growths or organic prostatic disease? Please omit name.

M.D., California

ANSWER—If such cases exist they are in all probability due to the reaction of the urine. Acid urine may cause such irritation. Drugs that reduce the acidity of the urine or throw it over to an alkaline reaction, such as sodium citrate or sodium bicarbonate, may relieve this.

VACCINATION SCAR AS SIGN OF IMMUNIZATION

To the Editor—Is it possible for a patient to receive immunity to smallpox even though a scar or take does not result after two vaccinations? Kindly omit name.

M.D. Oklahoma

ANSWER—While the possibility of some immune reactions to the virus introduced at the time of vaccination cannot be denied, preventive immunization against smallpox is dependent on the local and general reactions characteristic of successful vaccination. A person who has been vaccinated twice without a take is not protected against smallpox.

SIMULTANEOUS IMMUNIZATION

To the Editor—I was much interested in your reply to the question regarding simultaneous immunizations (*THE JOURNAL* April 14, p. 1251 and April 21, p. 1326). I have always felt that it was only rational to carry out a single procedure at a time, as you suggest. Dr. Leake presented an outline in *THE JOURNAL* Jan. 28, 1928, where rapid immunization for a number of diseases seemed to be necessary. Now that general practitioners are becoming more and more interested in preventive work, they seem to feel it necessary to reduce the routine that has previously been followed and combine all immunizing practices in one single dose. I grant you that if this were a correct procedure it would be highly desirable. As it never seemed to me a scientific procedure to ask the same set of cells to manufacture two or more specific antibodies at one and the same time, I wrote fifteen or twenty outstanding men in this country regarding it and received some interesting replies. To my surprise the laboratory men (no less than McCoy of the United States Public Health Service, Young of Michigan and others) almost unanimously were of the opinion that there was no reason why two or more immunizing agents should not be given at the same time. Dr. Hektoen of Chicago felt that he would hesitate about giving smallpox vaccination with other immunizing agents as in that case one would be dealing with a live virus; otherwise there would be no objection. To Major Hitchens at Fort Sheridan it seemed to be a live subject and he hoped that some one would be interested and that they would carry out measured experiments.

I. F. THOMPSON, M.D., Racine, Wis.

Commissioner of Health

DERMATITIS DUE TO SPUN GLASS

To the Editor—On page 1245 of *THE JOURNAL* of April 14 appears a question in regard to a dermatitis due to spun glass. In the answer it is stated that this condition has not been mentioned previously in the literature. I encountered the following reference which is a brief discussion and report of a single case and may be of interest to your correspondent:

von Szentkalyi, S. *Dermatitis artificialis durch Engelhaare*. *Dermat. u. chnisch* 93:1302 (August 15) 1931.

Rhode Island January Report

Dr Lester A Round, director, Rhode Island Public Health Commission, reports the written and practical examination held at Providence, Jan 4-5, 1934. The examination covered 7 subjects and included 70 questions. An average of 80 per cent was required to pass. Six candidates were examined all of whom passed. The following schools were represented:

School	PASSED	Year Grad	Per Cent
Georgetown University School of Medicine (1933)	83 9	84 8	88*
Boston University School of Medicine (1933)			86 4*
Tufts College Medical School (1929)	84 2	(1932)	83

One physician was licensed by endorsement on January 11. The following school was represented:

School	LICENSED BY ENDORSEMENT	Year Grad	Endorsement of
Boston University School of Medicine (1931)	N B M Ex		

*License withheld pending completion of internship

Wyoming Reciprocity Report

Dr W H Hassed secretary, Wyoming State Board of Medical Examiners reports 2 physicians licensed by reciprocity at the meeting held in Cheyenne, Feb 19, 1934. The following schools were represented:

School	LICENSED BY RECIPROCITY	Year Grad	Reciprocity with
Northwestern University Medical School (1933)			California
Marquette University School of Medicine (1933)			Wisconsin

Book Notices

Annual Reprint of the Reports of the Council on Pharmacy and Chemistry of the American Medical Association for 1933 with the Comments That Have Appeared in The Journal. Cloth Price \$1. Pp 188. Chicago American Medical Association 1933.

A feature of marked current interest in this volume is the preliminary report on alpha dinitrophenol the new drug for acceleration of cellular metabolism. The Council voices a warning on the dangers attending the use of this drug, this warning has been increasingly justified in reports of fatalities since the appearance of the Council's report in July of last year. Other preliminary reports which make this volume one of the most interesting issued by the Council in recent years are those on Dilaudid a new narcotic drug related to morphine. Tuadin, a new antimony compound for use in the treatment of bilharziasis and granuloma inguinale, and Hippuran, a new product for intravenous and oral urography.

The comprehensive and definitive special report on estrogenic substances furnishes a much needed review of the present status of such products in gynecologic therapy. The Council insists on the doctrine that basic laboratory investigation of these substances should precede clinical use. With the report on antipneumococcus serum containing type II antibodies, the Council in the light of recent improvement in preparations and technic puts its stamp of approval on the experimental use of type II antibodies as well as type I antibodies, which have been previously the only organisms of this kind recognized by the Council as worthy of clinical trial. Of interest to hospital authorities especially in connection with the book Hospital Practice for Interns recently issued by the Council in collaboration with the Council on Medical Education and Hospitals is the special report The Hospital Formulary, by Hatcher and Stamsby of New York. It outlines a plan characterized by the highest regard for the principles of rational drug therapy. Of more general interest is the Council's second

report on the intravenous use of barbitol compounds, which is the result of a questionnaire sent to representative physicians. In view of the answers to the questionnaire, the Council reaffirmed its previous decision concerning the limitations of intravenous use of barbitol compounds, namely, that these preparations should be administered intravenously only in a limited number of conditions in which administration by other routes is not feasible. The report carefully details these conditions.

The comparatively large number of reports on articles omitted from New and Nonofficial Remedies shows that the Council has recently been much concerned with products for which the original promise of therapeutic usefulness has not been fulfilled. Witness the omission of *Bacillus Bulgaricus* and *Kefir Fungi Preparations*, *Benzyl Benzoate*, *Benzyl Fumarate*, *Benzyl Succinate*, *Optochin Base*, *Pyridium*, and *Thiosinamine*, all of them for the reason stated. The lengthy report on the omission of *Pyridium* is an example of the meticulous fairness characteristic of the Council's treatment of the manufacturers of commercial preparations. In connection with the omission of *Pyridium* should be noted the report which declares *Azophene* (*Mallophone*) not acceptable. This product has been shown to be identical with *Pyridium* and the Council considers the claims for its usefulness as a local, general or urinary antiseptic as unwarranted as are those for *Pyridium*.

The main bulk of the volume, which, incidentally, is considerably increased over that of recent annual volumes, is taken up with reports on products which the Council has found unacceptable for inclusion in New and Nonofficial Remedies. Of special note are the report on *Alpha-Lobelin*, a drug on which the Council in 1927 issued a preliminary report but which is now found not to have established itself as a respiratory stimulant of as great usefulness as carbon dioxide and oxygen, the report on a number of preparations marketed by the Upjohn Company with unwarranted misleading and unscientific claims the report on *Clavipurin*, a preparation of the alkaloids of ergot, marketed without adequate declaration of the composition and without adequate standardization under a nondescriptive proprietary name with unwarranted therapeutic claims, the report on *Diampysal*, another pyridine derivative proposed for use in bacterial infections, convincing evidence for the therapeutic value of which is lacking, the report on *Euphydigital*, an irrational mixture of digitalis and a theophylline preparation marketed under an uninforming proprietary name with exaggerated and unwarranted claims for its therapeutic value, the report on *Guphen*, stated to be the guaiacol ester of phenylcinchonic acid marketed with unwarranted therapeutic claims under an uninforming proprietary name and having no proved advantage over its constituents administered separately, the report on *Niazol*, another pyridine compound of unsubstantiated value as a urinary antiseptic, the report on *Omnadin*, a preparation recognized for use for non-specific lipoprotein therapy practically as a cure-all, and the report on a group of endocrine preparations of the Roan Laboratories variously unacceptable as being of indefinite composition and of undemonstrated therapeutic value.

The Practitioners Library of Medicine and Surgery Volume V Traumatic Surgery [George Blumer Supervising editor] Associate editor Theodore S. Moose Jr. B.A. M.D. Surgeon to the Eastern Maine General Hospital Bangor. Cloth Price \$10 per volume Pp 1080 with illustrations. New York & London D Appleton Century Company 1934.

The Practitioners Library of Medicine and Surgery Volume VI Obstetrics and Gynecology [George Blumer Supervising editor] Associate editor Luther K. Musselman B.S. Ph.D. M.D. Associate Clinical Professor of Obstetrics and Gynecology Yale University School of Medicine. Cloth Price \$10 per volume Pp 800 with illustrations. New York & London D Appleton Century Company 1934.

These new additions to the Practitioners Library are on a par with the previously published volumes. They constitute essentially individual systems of "Traumatic Surgery" and "Obstetrics and Gynecology." The authors have been selected from a variety of institutions and have developed the topics they discuss according to simple and systematic outlines. The publisher has been extraordinarily generous in the provision of illustrations. The volume on "Obstetrics and Gynecology" is competent. The authors chosen are thoroughly familiar with the most recent literature of their subjects and the bibliographic references include not only recent contributions but also classic

contributions of an earlier day. If there is any special characteristic of these two volumes, it is the uniformly high character of practically all the contributions. It is rare in systems of such scope to find such an evenness of quality as is here apparent.

Studies in the Psychology of Delinquency. By Grace W. Palithorpe. Medical Research Council Special Report Series No. 170. Paper. Price 2s. Pp. 113. London: His Majesty's Stationery Office, 1932.

This study in the psychology of delinquency gives the result of investigations made on the recommendation of the Committee on Mental Disorders of the Medical Research Council of Great Britain. The material has been gathered over a period of five years from the inmates of prisons and of preventive and rescue homes. The study represents a combination of clinical and statistical approach and as such it is methodically superior to such statistical studies in criminology as do not investigate in detail the individual cases that serve as the basis of statistical calculations. The writer emphasizes the fact that, in contrast to most authors in this field who chiefly utilize methods of measurement and comparison instead of the most fundamental applications of psychopathology to individuals, she attempts to apply the analytic principles and refers to the similar efforts of Alexander and Staub in Berlin and of Aichhorn in Vienna. Although in the author's individual work with criminals there was no opportunity for formal, deep analysis of individual cases, she adopted the "simple but revolutionary expedient of letting the subject tell her own story, leaving first of course removed all possible obstacles to or obvious sources of bias in the recital."

The first part of the book consists in a comparative investigation of 100 female inmates of seven preventive and rescue homes in London. The cases were investigated by the standard methods of intelligence testing and with the method of prolonged interviews, approaching somewhat the psychoanalytic interviews. The second series of investigations was carried out on 100 female inmates of preventive and rescue homes and contains, apart from psychologic analysis, environmental studies, the results of which are also statistically worked up. It is noteworthy that in fifty out of a hundred cases satisfactory homes have been found and in only nine cases vicious homes. The high proportion of psychoneuroses and mental conflict, 55 per cent, is similarly of great interest. The second part of the book deals with case histories. The method adopted for taking case histories does not entitle one to expect a deep insight into the emotional development of the cases. But the case histories are intelligently recorded and show that the author's eye has been trained for observing relevant material. In summing up her results, the author states that there are 111 cases in 200 which need psychologic treatment in some form or other, and this figure excludes mental defectives and constitutional inferiors. Apart from treatment, segregation or supervision is also necessary.

Regarding sentiment development, the author recommends experimentation with intensive social education and psychoanalytic treatment. She suggests four general methods for dealing with the offenders: (1) segregation, (a) permanent, (b) temporary, (2) permanent supervision without loss of freedom, (3) education, (4) psychotherapy. Regarding the group that suffers from mental conflict or epilepsy and also displays psychotic tendencies before any definite psychosis has developed, the author first recommends full psychologic investigation. The investigator would then be in a position to advise (1) a specialized environment, educative or otherwise, (2) suggestion, direct or indirect, (3) psychoanalytic treatment. The author says that in 19 per cent of all cases of this group psychoanalytic treatment seems to be indicated.

On the whole, apart from some details, this study will be approved of by all physicians and criminologists who have accepted the principles of modern dynamic psychology. The relatively small number of investigated cases does not allow far-reaching statistical conclusions, but because of the careful individual study of the cases which are considered in the statistical charts this little study is much more valuable than most statistical studies in this field, in which criminality is usually taken as a unit in a mass of statistical data which are partly based on police records or on other inadequate sources of knowledge of the individual cases.

La diathermie et ses applications médicales. Par le Docteur Paul Duhem. *Electroradiologiste de l'Hôpital des Enfants Malades.* Second edition. Paper. Price 20 francs. Pp. 147, with 37 illustrations. Paris: Gauthier Villars, 1933.

This is an enlarged and completely revised edition of a work forming one of the nineteen monographs on facts of physical therapy, edited and in this instance written by Duhem. It follows in general outline the style laid down for the entire series, presenting the available theories and proved facts of diathermy and its medical practice with the least amount of circumlocution. To accomplish this and to keep it within its present size, a great deal of detail has been sacrificed in order to stress the basic facts and principles on which this discipline is founded. Discussions are therefore concise, the subject matter having that orderly arrangement of sequence—theory preceding practice—which makes it a practical exposition on the subject. In the space of seven chapters the author has managed to present in rough outline the historical background of high frequency therapy, its physical principles and electrophysiologic data, even to the point of bringing these down to date by a sketchy but, nevertheless, concise review of the promising possibilities of electroparalysis and short wave therapy. That the practical side has not been neglected is indicated by the fact that nearly half of the subject matter is devoted to discussions of its therapeutic action, the author stressing principles above specific indications, rather than dogmatizing on individual conditions. One closes the book with a conviction that here has been presented a valuable summary of diathermy and its medical applications from the point of view of an individual who has obtained his information from the country in which the therapeutics of the high frequency current was discovered.

Leadership in Medicine. By Lord Moynihan. Walker Trust Lectures on Leadership No. IV. Delivered before the University of St. Andrews, 16 February, 1933. Paper. Price, 2s. 6d. Pp. 48. London & New York: Oxford University Press, 1933.

The Oxford University Press here makes available in forty-eight pages of large, widely spaced type an essay by Lord Moynihan. Admirers of the literary style and of the philosophy of Lord Moynihan—and who is not—may wish to have the essay in this handsome form and consider the dollar well spent. The essay is built about the contribution of Lord Lister as contrasted with that of political and military leaders of mankind. It leads to the conclusion that science has assumed responsibility for leadership in industry and that what is now needed is introduction of the scientific method into the government of affairs.

Synopsis of Obstetrics and Gynecology. By Aleck W. Bourne. M.A. M.B. B.Ch. Senior Obstetric Surgeon, Queen Charlotte's Hospital, London. Fifth edition. Cloth. Price \$5.25. Pp. 439, with 175 illustrations. New York: William Wood & Company, 1932.

For the student desirous of rapid review in preparation for examination, Bourne's synopsis will be found of valuable assistance. It is written in outline form, well systematized, and illustrated with adequate line diagrams. In the new material in this edition the Stockholm treatment with radium for carcinoma of the cervix is fully outlined. The English school of teaching is strictly followed, so that in certain subjects, such as forceps, some variance from American practice will be observed. In general, however, the subjects are outlined in wholly acceptable form. The type is small with boldface headings. An adequate index is appended.

A Text Book of Gynaecology for Students and Practitioners. By James Young D.S.C. M.D. F.R.C.S.E. Gynaecologist, Royal Infirmary, Edinburgh. Third edition. Cloth. Price \$3.75. Pp. 411, with 220 illustrations. New York: The Macmillan Company, London: A. & C. Black, Ltd., 1933.

This is an almost complete revision of the previous editions. The chapters on physiology, disorders of menstruation, uterine hemorrhage and sterility have been completely rewritten. This well written and concise volume is an excellent textbook for students. However, the space devoted to operative gynecology might well have been devoted to an elaboration of certain chapters that have suffered by their brevity. The section on operative procedures is so incomplete and poorly presented that its omission would have been a distinct improvement.

Miscellany

RECENT DEVELOPMENTS IN PHARMACOPEIAL VITAMIN STANDARDIZATION

During the revision of the U S P X it became apparent that the newly discovered fat-soluble vitamin A should be recognized as an important factor in the potency of cod liver oil. It was also being demonstrated that "the antrachitic factor" should be given consideration, but at that time it had not been sufficiently studied so that there was knowledge of how to evaluate it. A group of those active in developing vitamin knowledge, including Drs Sherman, McCollum, Anderson, Holmes and the late Alfred F Hess, were invited by the Pharmacopeia Committee to suggest the basis for the new U S P text, they developed the first standard vitamin A assay method (1924) (U S P X, p 263) and this is still essentially correct. In setting a vitamin A standard for cod liver oil, these early workers realized that no one then knew what was the potency of an "average oil," so they required only a minimum amount (50 vitamin A units) primarily to exclude the cod liver oils then on the market, which were being purified and bleached by chemical methods, with destruction, thereby, of all vitamins.

In the period following 1926 when the U S P X became official, the scientific knowledge concerning vitamins advanced rapidly, so that in 1930 it was realized that the U S P standards were entirely inadequate. Steps were taken to issue a new text by "interim revision."

The U S P board of trustees appropriated an initial \$1,000 toward the expense and the Pharmacopeial Vitamin Committee was organized and the first meeting called in New York, under the auspices of the U S P Committee of Revision and presided over by the chairman of that committee.

The conference agreed on the general methods of assay for vitamins A and D, adopting in the main the details that had already been carefully developed by a vitamin committee of the American Drug Manufacturer's Association. The committee adjourned after a full day of discussion, having reached practically a unanimous agreement on all points. The committee also appointed Drs McCollum and Steenbock as their representatives at the International Vitamin Conference, called in London by the Health Organization of the League of Nations.

Some months later, the London conference having been held and its deliberations and conclusions released, a second meeting of the U S P Vitamin Committee was called in New York, again with a large group, about thirty-five participating. Again the government representatives, the leading experts in the vitamin sciences in this country and members of the scientific staffs of pharmaceutical manufacturers were present at the invitation of the Pharmacopeia. The committee agreed that the U S P should adopt as its standards the "International Vitamin Units."

To carry out the decisions of the larger committee and to serve specifically as an advisory group for the Pharmacopeia the U S P board of trustees established the U S P Vitamin Advisory Board and appointed as members, Dr Lafayette B Mendel of Yale University, Dr H C Sherman of Columbia University, Dr E M Nelson, director of the Vitamin Laboratory of the Food and Drug Administration, Prof E F Kelly, secretary of the American Pharmaceutical Association representing the Trustees and E Fullerton Cook, representing the U S P Committee of Revision.

THE INTERNATIONAL STANDARDS

By this time the Health Committee of the League of Nations had released and sent to this country a limited amount of the international vitamin A standard in the form of carotene and the international vitamin D standard, a special irradiated ergosterol both of these having been prepared at the British Institute for Medical Research under the direction of Sir Henry Dale.

THE U S P REFERENCE COD LIVER OIL OF KNOWN VITAMIN A AND VITAMIN D POTENCY EXPRESSED IN THE NEW U S P UNITS (INTERNATIONAL UNITS)

There being only a limited amount of this international standard available, the vitamin board immediately undertook the preparation of a sufficient quantity of a cod liver oil of known vitamin potency to be used as the basis for the standardization of American preparations claiming A or D vitamin potency.

The vitamin board secured the cooperation of the Bureau of Fisheries at Washington, which supplied a sufficient quantity of authentic cod liver oil, collected and destemmed under the supervision of the government laboratory in Gloucester, Mass. This oil was immediately placed in 30 cc amber-colored glass containers under rigid conditions involving the drying of the container and oil to eliminate all water, the exclusion of all air by vacuum, the introduction of carbon dioxide and hermetic sealing, independent of the screw cap.

This packaged oil was immediately placed in cold storage at a temperature under 15 C. Previous experience had shown that under such treatment and storage no deterioration in cod liver oil could be detected over a long period. Nevertheless the plans of the vitamin board include a reassay of this oil every six months for both its vitamin A and vitamin D potency.

To determine the initial vitamin activity of the "reference or standard cod liver oil," the board arranged with seventeen "vitamin laboratories" to assay this bottled oil, following exactly the assay methods adopted by the large vitamin committee. The board supplied added information made available by the International Vitamin Committee and supplied uniform report blanks, including graphs. All laboratories reported only by code number, the chairman of the board alone holding the key.

One set of assays was arranged for in London in the laboratory of Dr Coward, another in Oslo, Norway, under Dr Poulsen at the National Vitamin Laboratory, another at Johns Hopkins, another at Columbia University, another at the University of Wisconsin, and the others by well known vitamin experts many of them directing commercial laboratories. The board paid for two of these assays and all others were voluntary. When it is realized that the average cost of a vitamin A assay is \$280 and a vitamin D assay \$80 and that many laboratories ran from two to five assays on this one sample, the extent and value of this cooperation can be estimated.

Another significant feature of the program is the fact that with the promulgation of the new U S P vitamin standards and assay methods, most of the important vitamin laboratories in this country and even in producing countries abroad will already be thoroughly familiar with the details of the new U S P assay.

Fifteen of the seventeen laboratories have reported and the other two have the assays under way. The vitamin board has painstakingly studied and evaluated the reports and has recommended the following standards for the official cod liver oil.

Minimum Standard for Vitamin A for U S P Cod Liver Oil—The minimum vitamin A standard for U S P cod liver oil shall be not less than 600 international units.

Minimum Standard for U S P for Vitamin D Cod Liver Oil—The minimum vitamin D standard for U S P cod liver oil shall be not less than 85 international units.

NOTE—The new "U S P vitamin A units" and "U S P vitamin D units" are identical with the corresponding "international units." In expressing on labels the potency of vitamin-containing products, it is recommended that the term "U S P vitamin A units" or "U S P vitamin D units" be employed. To indicate the adoption of the new standards, the statement "U S P X—revised 1934" may be used.

For the benefit of those who wish to know the approximate relationship between units they are now using and international units of vitamins A and D, the following information is provided.

One U S P X Sherman or A D M A unit of vitamin A equals approximately 14 international or new U S P units.

One Steenbock unit of vitamin D equals approximately 27 international or new U S P units.

One international or U S P unit of vitamin D equals approximately 325 A D M A units. Or to phrase it another way, the new U S P minimum standard of 600 U S P Vitamin A units per gram is approximately equivalent to 428 "old" U S P A units, and the new 85 U S P Vitamin D per gram is approximately equal to 315 Steenbock or 276 A D M A units.

The U S P board of trustees has also announced the release of the "reference cod liver oil," prepared under the supervision of the vitamin board, for use in the standardization of medicinal or food products claiming vitamin potency, and already many laboratories in this country have secured this official vitamin standard. These new U S P standards of vitamins A and D will be the basis for the evaluation by the Food and Drug Administration of all products in the country claiming vitamin A or D potency.

Copies of the U S P X (1934) interim revision Cod Liver Oil Text or the Reference Cod Liver Oil may be obtained by addressing the Chairman of the Committee of Revision

Medicolegal

Workmen's Compensation Acts Industrial Commission May Not Order Attorney to Pay Medical Witness' Fee—The state industrial commission of Oklahoma ordered a certain fee to be paid to a claimant's attorney and directed the attorney to pay out of this sum the witness fee of the physician who testified for the claimant in the case. It was contended that the commission erred in ordering the attorney to pay this witness fee. We regard this contention as serious, said the Supreme Court of Oklahoma. Attorneys are permitted to practice before the state industrial commission. Their fees must be approved by the commission before they become a lien on the compensation awarded. Attorneys should be accorded the same fair consideration in fixing the amount of their fees for appearing and conducting litigation before that body as they usually receive before any other tribunal, considering the amount of legal work done and the amount of money involved. The question of the reasonableness of the fee is a discretionary matter with the commission, and unless this discretion is abused the award should be upheld. For the commission, however to direct that a lawyer pay a portion or all of the expense of a client's litigation is highly improper. It would not be sound policy to permit the commission to order the mingling of attorneys' fees and medical fees. It might lead to the encouraging of litigation, collusion, and framing of evidence, and might tend to make a medical witness feel that his remuneration in the case would depend on the result of the commission's decision. The Supreme Court therefore declared void that portion of the award of the industrial commission directing payment of the witness fees out of the attorney's fees.—*Willhite v Prairie Oil & Gas Co (Ola)* 26 P (2d) 406

Workmen's Compensation Acts Aggravation of Pre-existing Heart Disease Compensable—In the course of his employment the employee pushed up a grade tramway cars loaded with coal. After pushing one car containing a somewhat heavier load than usual, he appeared out of breath, evidenced extreme distress, sank to the ground and died within ten minutes. In a proceeding instituted by his widow under the Tennessee Workmen's Compensation Act physicians testified that the death resulted from acute dilatation of the heart, which, in their opinion, was likely to result from overexertion. Proof was adduced however, that prior to the alleged industrial accident the employee had "a chronic condition of heart weakness." The employer insisted that death was not due to an accident but rather to this disease condition of the employee's heart. The trial court awarded compensation to the widow and the employer appealed to the Supreme Court of Tennessee. We are of the opinion said the court that under the facts shown here the award of the trial court was proper. In *Tennessee Eastman Corporation v Russell* 150 Tenn 334, 265 S W 540, the court approved of the general rule of law that

in proceedings under the workmen's compensation act "a pre-existing weakness or disease will not prevent the injury from being the result of an accident, if the accident is the immediate cause of the injury." In *Brightman's Case*, 220 Mass 17, 107 N E 527, L R A 1916A 321, it was held that the acceleration of a previously existing heart disease to a mortal end sooner than it otherwise would have come was an injury within the meaning of the Massachusetts workmen's compensation act. The award in favor of the widow was affirmed.—*Cambria Coal Co v Ault (Tenn)*, 64 S W (2d) 18

Current Medical Literature

AMERICAN

The Association library lends periodicals to Fellows of the Association and to individual subscribers to THE JOURNAL in continental United States and Canada for a period of three days. Periodicals are available from 1925 to date. Requests for issues of earlier date cannot be filled. Requests should be accompanied by stamps to cover postage (6 cents if one and 12 cents if two periodicals are requested). Periodicals published by the American Medical Association are not available for lending but may be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

Titles marked with an asterisk (*) are abstracted below.

Alabama Medical Association Journal, Montgomery

3 293 332 (March) 1934

Cancer of Larynx. Report of Three Cases of Laryngectomy M. E. Quen Atlanta, Ga.—p. 293

*Treatment of So Called Intestinal Intoxication of Infants. Comprehensive Plan A. C. Gipson, Gadsden—p. 296

Drifting Sands of Medical Practice J. S. McLester Birmingham—p. 305

Ankle Fractures R. Carothers, Cincinnati—p. 309

Pelvic Inflammation in Women G. F. Douglas Birmingham—p. 311

Treatment of Intestinal Intoxication of Infants—Gipson outlines a plan of treatment in cases of intestinal intoxication in infants. Ringer's solution is given intraperitoneally or subcutaneously or both ways. As quickly as possible, blood is taken from the baby and from relatives or friends in order that they may be cross-matched. A blood transfusion by the citrate method is done, the amount of blood given varies from 10 to 30 cc. per pound of body weight, transfusions seldom total less than 100 cc. or more than 200 cc. If the patient has acidosis, the stomach is washed and from 45 to 90 grains (3 to 6 Gm) of sodium bicarbonate dissolved in from 40 to 60 cc. of ice cold water is left in the stomach. This treatment may be repeated once or twice, according to indications, at intervals of three hours. Water is given by mouth, either in fixed amounts at definite intervals or continuously by the drip method through a nasal catheter. Ringer's solution is administered parenterally as often as it is indicated. Transfusion may be repeated once or twice at intervals of twenty-four hours if the child does not improve. No food is given by mouth until toxic symptoms have disappeared or greatly diminished. When food is given, the interval is two hours, and the caloric value is raised daily by small increments. On the first day a total of about 50 calories is given, on the second 75 on the third 100, and so on. The increments may then be made larger and the total caloric requirement attained in a week or ten days. Modification of the procedures as regards feeding is made when the patient is an atrophic baby with severe infection.

American Journal of Cancer, New York

20 539 790 (March) 1934

Dilatations of Cavity of Septum Pellucidum and Cavum Vergae. Report of Cases W. P. VanWagenen and R. B. Aird, Rochester, N. Y.—p. 539

Effect of Radium on Spinal Cord. Report of Two Cases of Myeloma W. T. Peyton, Minneapolis—p. 558

Nematode and Carcinoma in Human Kidney Pelvis A. Plaut, New York—p. 610

Tumor Amylase. General Properties and Estimation of Activity F. H. Charles and W. T. Salter, Boston—p. 613

Id. Effect of Various Hormones and Chemical Agents F. H. Charles, Phoebe D. Robb and W. T. Salter, Boston—p. 625

Effect of Testicle Extract on Animal Neoplasms F. Prime and C. D. Haagenen, New York—p. 630

Metastasis of Melanoma Four Years Before Appearance of Primary Lesion—Selig presents the case of a non-pigmented melanoma of the right heel metastasizing to the groin four years before the primary growth was visible. The early

metastasis may have been due to the constant trauma to which the growth was subjected because of its location. The tumor was resistant to roentgenotherapy. A lymph node metastasis was the first evidence of the disease, and a careful search of the skin over the area drained by the involved node failed to reveal the primary growth until more than four years had elapsed.

Complications Resulting from Pelvic Irradiation for Cancer—Findley points out that complications, such as pyometra, parametritis and thrombophlebitis, are found in cases of cancer of the cervix after radium irradiation. The primary mortality of radium therapy is generally conceded to be about 2 per cent and is largely due to an awakening of an unrecognized latent infection within the pelvic structures or to direct contamination of the field of irradiation. When there is evidence of active pelvic infection, a period of rest should precede irradiation, together with such local applications as will favor the elimination of infection. When symptoms of cystitis arise shortly after irradiation, it is assumed that there was a pre-existing and possibly unrecognized chronic cystitis, as cystitis does not usually manifest itself for from two to four weeks following irradiation. The usual edema and congestion of the mucosa of the bladder incident to irradiation rarely persists beyond from two to four weeks, but there are aggravated cases in which lesions of a serious nature develop one or more than one year later. Fistulas and fixation of the bladder are the end stages of a most distressing condition. In all this there is evidence of excessive irradiation and the lack of precautionary measures in protecting the bladder from direct exposure to the

rays Chronic vaginitis, with the formation of adhesions between folds of the vaginal walls, is a late development and is largely confined to the postmenopausal period. Here, again, excessive dosage and inefficient screening are responsible. The rectum is most often the seat of postirradiation sequelae: proctitis, diarrhea, tenesmus, ulcers, fistulas and strictures. Pelvic irradiation for therapeutic purposes, in the presence of an unsuspected pregnancy or when done for the relief of conditions known to complicate a recognized pregnancy, is a serious matter. Irradiation of the early fetus results in such deformities as microcephalic idiocy, microcephaly, hydrocephalus, blindness, spina bifida, clubfoot, alopecia of the scalp, ossification defects of the skull, divergent squint, and deformities of the upper extremities. The likelihood of such deformities has led Norris to advise the interruption of pregnancy when it is disclosed that an unrecognized pregnant uterus has been irradiated for therapeutic purposes. An exploratory curettage preceding pelvic irradiation in the childbearing age as a precautionary measure would be advisable. Cancer of the cervix associated with pregnancy should be treated in the interests of the mother in the early stages of cancer. In the late stages the interest of the baby is the prime consideration and radium therapy is the method of choice. Because of the danger of infection and of injury to the fetus, the uterus should be emptied before radium is applied.

Amenorrhea and Low Basal Metabolic Rates—Mussey and Haines discuss a small series of cases in which there was a low basal metabolic rate without evidence of myxedema and in which amenorrhea or oligomenorrhea occurred and a pathologic cause could not be found in the pelvis. Clinical observation has shown that either an excessive or an inadequate supply of thyroxine may definitely be associated with disturbed menstrual function. Thyroxine is essential to normal cellular metabolism, and this may be its only mode of action on the ovary. A study of twenty-seven patients having amenorrhea or marked oligomenorrhea failed to disclose any organic disease to which the menstrual disturbance could be attributed. Basal metabolic rates were raised by the administration of an active preparation of desiccated thyroid administered orally each day. After a suitable dosage had been determined for a metabolic rate of from -5 to -8 per cent, the patients were allowed to return home to continue the treatment with desiccated thyroid. The condition of thirteen of the twenty-two patients having amenorrhea was improved after treatment. The improvement of most patients was marked, and the menstrual periods of seven were reestablished to normal intervals and in normal amounts. The longest duration of amenorrhea of any patient who was better after treatment was one year. Of the five patients having oligomenorrhea, two were better after treatment, two were not helped, and one had a more scanty menstrual flow. Twenty-five of the twenty-seven patients complained of fatigue or functional disturbances, which, in many instances, had preceded the menstrual disturbances by years, twenty-one of which expressed themselves as in better general health after elevation of the basal metabolic rate.

Diphtheria Toxoid—Levin and Cary gave a preliminary Schick test to 1,016 children, 84 per cent of whom were in the 4 to 10 year age group. None of these children so far

as could be determined, had had diphtheria or had been immunized against it. Three 0.5 cc injections of undiluted toxoid at weekly intervals gave 98 per cent of immunities. Practically no reactions were obtained with this size dose.

Visualization of Bronchi and Alveoli—Bendove and Gershwin state that, when iodized oil is injected intratracheally, it tends to delineate the bronchi and alveoli in an inverse proportion, i. e. the more the alveoli are outlined, the less the bronchi are visible, and vice versa. This inverse ratio in the visibility of the iodized bronchi and alveoli is of diagnostic significance. In a normal lung the outlined alveolar element predominates, overshadowing all the bronchi, and the roentgenographic image simulates a tree in midsummer. Diseased and dilated bronchi retain most of the injected material, and few, if any, of the alveoli in the corresponding territory will be delineated on the roentgenogram. In cases of extreme cylindric dilatation, the filled bronchi resemble the branches of a tree in winter with no remnant of the former foliage. The absence of the alveolar leaves may be general or localized, depending on the extent of the bronchial dilatations. Any bronchus that retains the iodized oil fifteen minutes after its injection is to be considered functionally impaired, irrespective of its morphologic appearance. In order to maintain definite standards of comparison, it is advisable always to inject 20 cc of the iodized oil and to outline only one lobe at a time.

Roentgen Treatment of Benign Hypertrophy of the Prostate Gland—Barringer and his associates tried high voltage roentgen therapy in thirty-four cases of hypertrophied prostates. They observed that in 30 per cent of cases which otherwise would come to operation, high voltage roentgen irradiation reduces the residual urine and controls the symptoms. The edematous prostate entirely loses its edema under the treatment. A complete cystoscopic examination of the prostate is essential to determine the type of prostatic hypertrophy present. It is probable that the "simple bilateral lobe hypertrophy" so well described by Randall is the type most suited to respond to this therapy. In those patients, in whom for one reason or another, such as poor heart advanced age, bad kidney function, operative intervention of any kind is contraindicated, high voltage roentgen irradiation should be the therapy of choice. The technic of administering the dose selected has varied with the patient factors that enter into the selection of the dose and the method of administering it. The dosage at each exposure amounted to about 200 roentgens. The same series of treatments were repeated after an interval of ten days. The third cycle or even the fourth, is decided on after later urologic examinations. A small dosage has been given to decrease reactions. Repeated doses are given for the theoretical reason that this method produces more fibrosis.

Resection of Presacral Nerve for Dysmenorrhea—DeCoursey resected the presacral nerve in twenty-one cases for the relief of dysmenorrhea. The immediate results of the procedure have been excellent, and in no instance has the relief of pain failed. Menstruation regularly takes place within forty-eight to seventy-two hours after operation no matter at what time in the menstrual cycle it has been performed. Most of the patients have had to be catheterized for two or three days but the inhibition of bladder function has been no more marked than after any other gynecologic operation. None of the author's patients have had any difficulty with the bladder afterward, although the possibility of some interference with vesical function has always been kept in mind. Several of his patients have since become pregnant, demonstrating that there is no interference with child bearing.

Ileus Treated by Continuous Suction from Stomach—Since 1931 Bartlett has employed continuous positive suction of the stomach in eighteen patients having ileus. Suction was used as the only curative measure in some and as an adjunct to enterostomy in others. In every patient but one who developed ileus following an intra-abdominal operation evidence was found for the existence of peritonitis as the exciting factor by characteristic changes in the differential leukocyte count (Schilling), a clinical course which was febrile, at least in part and physical findings or postmortem observations when death ensued. Dilatation of the stomach was a relatively late phenomenon nausea and slight abdominal distention usually having already occurred, while intermittent aspiration of the stomach revealed only small amounts of fluid and gas and while the stomach continued to pass ingested fluid over the pylorus. When considerable handling of the abdominal viscera has been necessary ileus appears usually within twenty-four hours of the resumption of fluids by mouth, and it disappears rapidly after institution of continuous suction. In cases in which trauma and motor inhibition are minimal factors ileus develops after forty-eight or seventy-two hours as intraperitoneal infection becomes manifest and recedes more slowly after treatment is

started. The author feels it is undesirable that the nasal catheter pass through the pylorus into the duodenum. He urges the employment of continuous positive suction of the stomach as a curative measure. He has simplified Ward's apparatus for continuous suction. This apparatus permits one to know with mathematical accuracy the gastro-intestinal status of the patient, so far as function is concerned. Increasing experience with this treatment indicates that there is a large group of patients with intestinal obstruction in which the risk of death is far less if decompression of the intestine is brought about by continuous suction of the stomach than if operation is performed within more than a few hours of the onset.

Specific Vaccine in Treatment of Peptic Ulcer—During two years Hinton has treated seventy-two cases with intravenous vaccine, which included nine cases of acute perforation and eight in which operation was performed for chronic ulcers, leaving fifty-five nonoperative cases under treatment, and these were more favorably selected as they did not necessarily represent medical failures from other types of conservative treatment, of these, six were gastric, three pyloric and forty-six duodenal lesions. Cases in which the epigastric pain returned or was intensified for twenty-four hours following the injection offered the most favorable prognosis. The diet has been restricted and the author feels that it is best to place the patient on an ambulatory Sippy regimen in conjunction with the vaccine administration. In deciding the good results of the method he relies exclusively on symptomatic relief from pain, based on frequent visits to the clinic. He is sure that Saunders' vaccine has a definite place in the treatment of peptic ulcer.

Head Immobilization for Skull Roentgenography—Moore points out that the only equipment necessary to immobilize the head completely is two cushions, small enough so as not to obscure too much of the head, and stuffed with soft material packed tightly so as to make the cushions firm. When the patient is placed on the table with the face over the Bucky diaphragm, the arms are extended forward. The head is then placed in the desired position and following this the cushions are placed one on each side of the head. The arms are then drawn medially and the forearms crossed. This brings the upper arms snugly against the cushions and they in turn press these cushions firmly against the head. The hands then grasp the opposite forearms, producing a stable and comfortable position.

Blood Pressure Variations in Tuberculosis—Bunta made a total of 3,411 blood pressure determinations on 2,915 patients. Of the 1,671 nontuberculous subjects, free from signs of cardiovascular or nephritic disease, the systolic measurements varied from a minimum of 70 to a maximum of 154 mm of mercury. The mean pressure was 112 mm and the standard deviation was 53 mm, representing a normal systolic range of from 107 to 117 mm of mercury. Diastolic readings varied from 40 to 100 mm of mercury. The mean pressure was 72 mm and the standard deviation was 31 mm, defining a

normal diastolic pressure range of from 69 to 75 mm of mercury. Pulse pressures varied from 20 to 70 mm, the average being 42 mm with a deviation of 3 mm of mercury. Normal pulse pressure, therefore, ranged from 39 to 45 mm of mercury. Of the 1,244 patients comprising the tuberculosis group the systolic pressures varied from a minimum of 60 mm to a maximum of 276 mm of mercury. The mean pressure was 112 mm and the standard deviation was 21 mm, representing an average systolic pressure ranging from 91 to 133 mm of mercury. Diastolic readings varied from 30 to 152 mm of mercury. The mean pressure was 72 mm and the standard deviation was 7.6 mm, defining an average diastolic range of from 64 to 80 mm of mercury. Pulse pressures varied from 10 to 146 mm of mercury. The mean pressure was 37 mm and the standard deviation was 7.7 mm, describing an average pulse pressure range of from 29 to 45 mm of mercury.

 The Effects of Ultraviolet Irradiation on Rachitic Chickens G M Higgins C Sheard and R M Wilder Rochester Minn—p 205

Effect of Pregnancy on the Ovary—Selye and his associates state that both the gonadotropic hormone of the anterior pituitary and that obtained from the urine of pregnant women prevent the appearance of thecal deficiency cells in the ovaries of hypophysectomized rats. Hypophysectomy during gestation does not alter the corpora lutea of pregnancy in any way but does cause the thecal cells to show signs of hormone deficiency. Hence the unknown influence which maintains the structure and function of the corpora lutea of pregnancy is not identical with either of the known gonadotropic hormones.

Injection into Male Rats of Extracts of Pregnancy Urine—Smith and Leonard injected extracts of pregnancy urine over varying periods (from ten to sixty days) in hypophysectomized and normal mature and immature male rats. The injections in the hypophysectomized males either maintained testicular weights or profoundly slowed the atrophy that characteristically takes place after pituitary ablation. The treatments invariably produced an enlargement of the accessory reproductive organs and a hypertrophy of the interstitial tissue both in the normal and in the hypophysectomized males. In some of the normal animals this enlargement persisted for the duration of the injections, in others a regression of the accessories took place (sixty-two days). In all the hypophysectomized animals there was a marked regression of the accessories and the interstitial tissue by the thirtieth day of treatment. In mature hypophysectomized rats, injections maintained spermatogenesis, mating and fertility for the duration of the injections. In immature hypophysectomized rats, the development of the tubules continued and spermatids but not spermatozoa formed, though none were present at the time of operation. In both mature and immature hypophysectomized rats, injections begun after a period of from twenty to seventy-five days following operation induced a relatively great increase in the weight of the testicles, an enlargement of the tubules and an increase in the activity of the germinal epithelium. In only one of four treated animals were spermatids formed. The injections did not hasten maturity in normal males. The tubules were not injured in either the mature or the immature rats. In the mature males intratubular columns of typical spermatogenic cells were infrequently found. The treatments did not interfere with mating or fertility.

Injections into Female Rats of Extracts of Pregnancy Urine—Leonard and Smith observed the effect of injections of pregnancy urine on immature and mature hypophysectomized

female rats. Treatment begun at the time of operation increased or maintained the weights of the ovaries for a time, though regression took place with prolonged injections. Postponed treatment caused an invariable increase in the weights of the ovaries. Follicular growth was not induced by the treatments. The interstitial and theca cells hypertrophied and became much like lutein cells, causing a structural homogeneity of the ovary. The hypertrophy did not persist when the treatments were prolonged or stopped. It persisted however, in certain newly formed bodies which appear to be structurally identical with corpora lutea. Estrin was secreted by the ovaries in both the mature and the immature hypophysectomized animals injected immediately after the operation and in some of the postponed treatments. The effects induced by injections of pregnancy urine in hypophysectomized rats are dissimilar to those produced by anterior pituitary implants, the latter producing larger ovaries which contain normal and cystic follicles and larger corpora lutea. The effects of injection of pregnancy urine in hypophysectomized rats are also not the same as in normal rats, for in the latter there is a development of follicles, cysts and blood follicles. The pituitary sex hormone facilitates the action of pregnancy urine on the ovaries as shown by results obtained in partial hypophysectomies and in concurrent injections of anterior pituitary and pregnancy urine in hypophysectomized and in normal immature animals. The action of pregnancy blood serum is similar to that of the pregnancy urine extracts. Hypophysectomy followed by injections of pregnancy urine induces ovarian changes in rats which are strikingly similar, in many respects, to those produced by irradiation of the ovaries of adult mice.

 *Tuberculoma of the Brain M Lewison E B Freilich and O B Ragins Chicago—p 1141

The Hereditary Factor in Hypochromic Anemia with Achlorhydria—Barrow states that a review of the literature and of the case histories of hypochromic anemia with achlorhydria indicates that there is a not uncommon association of this type of anemia with primary anemia in members of the same family. A family history of secondary anemia of undetermined type is occasionally found, but proved reported cases of achlorhydric anemia in more than one member of a family are rare. The author has found no record of more than two cases in one generation. Of possible importance from the point of view of etiology is the evidence of a familial form of achlorhydria although there is no known relationship between this and achlorhydric anemia. The specific hematopoietic hormone of normal gastric juice recently demonstrated by Castle which is absent in pernicious anemia was found to be present in some cases of achlorhydric anemia. Nevertheless, nearly all contributors to the subject from Faber to the most recent writers, advance the theory that the anemia is secondary to a gastric secretion deficiency which results in an interference with the maintenance of normal hematopoiesis. A case history of achlorhydric hypochromic anemia is presented with actual or presumptive evidence of the same type of anemia in the patient's five sisters and in her mother and mother's sisters. There is nothing in the history or physical or laboratory observations

of these patients to suggest a common factor of etiologic significance. A second family is reported in which there seems to be a tendency to secondary anemia, but only one case was of the achlorhydric achromic type. If these cases are related etiologically, there is again no indication as to what the etiologic factor may be. One may only conclude that this type of anemia is not uncommonly found in families in which there is evidence of primary or secondary anemia in other members of the same family.

Tuberculoma of the Brain—In an analysis of 757 necropsies performed at the Cook County Hospital from 1917 to 1927 inclusive on patients who had died of tuberculosis, Lewison and his associates discovered twenty instances of tuberculoma of the brain. From the point of view of symptomatology the cases fall into two groups. In the first the symptoms are those of a space-occupying mass in the cranial cavity or spinal canal, i. e., the symptoms of increased intracranial pressure and those further localizing symptoms and signs that indicate the level of the lesion. In the second group of cases the most prominent clinical symptoms are those due to the coincident tuberculous meningitis, and these meningeal symptoms frequently completely mask the clinical evidences of the presence of tuberculoma. In seven cases the clinical diagnosis of tuberculous meningitis was made. In two instances tuberculoma of the brain was diagnosed. At necropsy meningitis was found in seventeen cases, in one a focal meningitis was reported and in two the meninges did not show any involvement. The sites in the brain at which the tuberculomas were found did not indicate any special predilection of this lesion for any certain area. There were eleven cases with one tuberculoma, four with two, two with three and three with multiple tuberculomas. In all cases tuberculous lesions were found in other organs of the body in addition to the lesions of the brain. The average age was 22.7 years, the youngest 15 months and the oldest 56 years. It was predominantly an adult group. There was an equal number of men and women in the group. There were sixteen cases in Negro patients, two in white and two in Mexicans.

Action of Saliva on Blood Coagulation and Wound Healing—The Ersners and Myers show that saliva when added to blood *in vitro* produced in numerous trials a reduction of blood coagulation time of from ten to fifteen minutes to one of from two to three minutes. The saliva, whether autogenous, exogenous mixed from various individuals centrifuged, using supernatant fluid or the sediment has the same effect in producing a reduction of the coagulation time. Saliva that has been kept on ice from twenty-four to forty-eight hours or at room temperature for this length of time has the same effect in decreasing the coagulation time, showing again that whatever agent is present does not become inert. Saliva, after continued stimulation (petrolatum chewing) retained its coagulating power and the *ph* of the saliva did not vary. Filtered saliva possesses the same coagulant action as whole saliva. The authors suggest that patients who are to undergo an operation be given sodium bicarbonate to neutralize gastric acidity and petrolatum to chew or some other inert substance

that will stimulate the salivary secretions, and be made to swallow this saliva, so that its presence will alkalize the gastric acidity as well as aid blood coagulation.

Osteochondritis Dissecans—Of Conway's ten cases of osteochondritis dissecans, eight involved the knee and two the elbow. The condition is more often seen in men than in women. The average age is from 15 to 35 years. The symptoms in the order of frequency are pain, disability, swelling and the presence of a movable body. The roentgenogram is usually pathognomonic and stereoscopic views of the affected joints are invaluable in the determination of the amount and degree of articular damage. The treatment is arthrotomy with the removal of the loose fragments, and the optimal time for surgical intervention is during the period of demarcation before any great degree of synovial change has occurred.

Dislocation of Cervical Vertebrae—Warshaw reports a case of complete forward dislocation in which full reduction of the dislocation was secured by forcible traction and counter-traction under anesthesia without subsequent immobilization. There was no injury of the spinal cord. A few peripheral nerves were involved. The author believes that the fact that the patient made a permanent recovery without any form of immobilization is of interest, in view of the prevailing view that hyperextension in some form of apparatus or plaster is necessary over a long period of time.

The Development of the Specific Nodule of Silicosis—To study the morphologic reactions provoked in the lung by particulate silica and by bacilli of tuberculosis, Lemon and

Feldman gave intratracheal injections to two series of rabbits. The animals were killed at intervals of from four hours to four weeks after receiving the respective inoculums, and the cellular response was studied histologically. The character of the cellular response to the irritative influences of particulate silica and to bacilli of tuberculosis was essentially the same, both promoted the formation of characteristic tubercles. The properties of the provocative agent responsible for the production of the silicotic tubercle precluded the formation of a structure characterized by continuous progression. This contrasts markedly with that formed as a consequence of the injection of bacilli of tuberculosis, which is usually of a progressive, destructive nature. The similarity of the structural unit or tubercle invoked experimentally in response to particles of silica and to bacilli of tuberculosis was so striking as to make their certain differential identification impossible by ordinary morphologic criteria. Although the pathologic characteristics of the two processes were practically identical during the early period of cellular progression, significant structural differences became evident as the duration of the diseases was extended.

Arteritis of the Temporal Vessels—Horton and his associates observed a woman aged 55 and a man aged 68 who complained of fever, weakness, anorexia, loss of weight, anemia, mild leukocytosis and painful, tender areas over the scalp and along the temporal vessels. The symptoms had been present from four to six weeks. Localized periarteritis and arteritis were present in each case. Study of the affected arteries indicated that the lesion probably began as periarteritis of a small segment of the artery. When the artery was palpated at this stage, segments from 1 to 2 cm in length were tender but pulsations were still present. What apparently happened was that the process subsided when it reached this stage, leaving the wall of the vessel thickened but patent, or the process continued, spreading into the surrounding tissue as well as to the media and intima, with thrombosis of the involved segment. Microscopic sections of the blood vessels removed for biopsy disclosed identical lesions. Both patients apparently recovered completely from the local condition, although one died approximately two years later from congestive heart failure and renal insufficiency. The bacteriologic studies were inconclusive. They believe that this report may represent a new clinical syndrome the etiology of which is still obscure.

Thrombo-Angitis Obliterans with Suprarenal Infarction—Birnbbaum and his associates present a case of generalized vascular disease, probably early thromboangitis obliterans, in which necropsy was possible early in the course because of the involvement of vital structures (the suprarenals). Involvement of the cerebral, retinal, pulmonary, coronary, mesenteric, suprarenal, pancreatic, duodenal, hepatic, renal and prostatic vessels and of the vessels of the extremities was found. The clinical manifestations of the changes and of the suprarenal apoplexy in this case are discussed. The possibility that thromboangitis obliterans is more frequently a generalized disease is pointed out.

Surgical Treatment of Concomitant Squint—Wilkinson presents his operations for concomitant squint in which all shortenings or recessions are accurately measured by calipers. In recession operations the position of the scleral stitch is

measured and marked in order that accurate placing of the stitch may be accomplished. In the resection operation he uses a central mattress suture similar to that described by Snellen, Ewing and Lancaster. This is brought out through the capsule and conjunctiva, as suggested by Duverger. This mattress suture secures a much stronger anchorage than is obtained by the Reese operation. The author has also devised a recession operation in which he does not use a scleral stitch and which he feels is safe and at the same time the most simple recession operation possible. He has performed twenty-five of these operations during the past two years and so far his results have been good. About 12 degrees of correction can be secured with a 4 or 4.5 mm recession, and the cosmetic and functional results are excellent.

- Influence of Extract of Anterior Pituitary on Autotransplanted and Homotransplanted Thyroid M Silberberg Breslau Germany—p 381

Histology of Adenoma of Islets of Langerhans—O'Leary and Womack verified five tumors of the pancreas, operatively removed, as islet cell adenomas, verifying in each case the preoperative diagnosis of hypoglycemia due to suspected tumor. Although the adenomas varied in size, gross appearance and apparent age, the majority cell type of each was closely allied to the beta cells of the normal islets of Langerhans but possessed definite tumor characteristics. In only one of the five tumors was there evidence of a malignant process. The staining reactions of the specific cytoplasmic granules in the majority of tumor cells of each deviated sufficiently from those of the beta cells of normal human islets to lend support to the hypothesis of dysinsulinism. In none of the cases did the histologic picture of the islets of Langerhans of the pancreas containing the tumor indicate the suppression of function that might be expected to parallel the prolonged secretion of excessive amounts of the hypoglycemic hormone.

Hepatic Changes from Obstruction of Common Duct—Lieber and Stewart describe the changes in the hepatic and bile ducts resulting from obstruction to the common bile duct by carcinoma of the head of the pancreas and submit evidence showing that cirrhosis may result from uncomplicated or non-infectious biliary stasis. The biliary conducting system undergoes a tremendous volumetric increase, with corresponding stretching and thinning of its walls. The process extends uniformly into the branches of the fourth and fifth orders. The vasa aberrantia and parietal sacculi become effaced. The canaliculi are distended with bile thrombi, many of which remain in place, although others are extruded into the tissue spaces and sinusoids, where they may be phagocytosed by Kupffer cells and macrophages. Bile pigment in the form of granules or droplets and in colloidal suspension may be found, chiefly in the cells of the central portions of the lobule. Regressive lesions are present as mild and localized degenerative changes involving the hepatic cells about the central vein, as nonpigmented focal midzonal areas of necrosis, and as deeply pigmented biliary necroses occurring either in the outer portion of the lobule or within the portal radicle. The intrahepatic ducts elongate and become tortuous, and they show, in addition, a true proliferation. A new formation of connective tissue occurs simultaneously with the changes in the bile ducts until after the second month, when a rapid, independent and progressive proliferation takes place, resulting in a well marked deposit of connective tissue, which is interlobular, intralobular and, in long-standing cases, even perilobular in distribution. The hepatic lobules show a corresponding reduction in size.

without much architectural alteration except at the peripheries, where atrophy may become well marked. The walls of the branches of the hepatic artery undergo hypertrophy and those of the branches of the hepatic vein and to a less extent of the portal veins show a new formation of fibrous tissue. The liver possesses little or no regenerative ability in the face of total stasis.

Treatment of Pituitary Infantilism with Anterior Lobe Extract—Goldberg reports the case of a boy of 17 who exhibited the cardinal features of pituitary infantilism. Coincident with a course of sixty-seven injections of a soluble extract from the anterior lobe of the pituitary the patient gained approximately 2 inches (5 cm) in height and showed objective evidence of an increased sex drive as well as personal aggressiveness. During an interval of ten weeks when treatment was omitted no growth occurred.

Studies of Suprarenals—Clark and Rowntree reviewed a series of 25,000 necropsies to determine the incidence of suprarenal disease. Beyond a surprising lack of interest in the suprarenals, as evidenced by mention of pathologic changes in only 925 instances nothing noteworthy or definitely new came of the survey. In a limited number of cases, however suggestive relationships were observed between chronic suprarenalitis and cardiorenal vascular disease and cortical atrophy associated with atrophy of the parenchymatous organs. The need for further investigation of tumors of the suprarenal is indicated to determine the cells of origin not only in those arising in the medulla but also in those cortical adenomas causing such marked changes in sexual characteristics.

Immunologic Studies in Case of Typhoid with Relapses—Thompson and Ecker cite a case of typhoid with two relapses, which is of interest because of a complete lack of agglutination and precipitation reactions in the course of the disease, while positive complement fixation and bacteriolytic and marked opsonic powers were observed, possibly indicating the final mechanisms of recovery. These results also appear to indicate a plurality of antibodies, but it is to be emphasized that the antigen is complex and that the question of unity or plurality of antibodies can be solved only by the use of a single and pure antigen. The case is also of importance in that serum failed to dissociate the organism and no bacteriophage was isolated. The organisms isolated proved to be typical typhoid bacilli (cultural and serologic) and stimulated the production of the O type of agglutinins in the rabbit.

 Allergic Manifestations of the Skin L J Owen Lincoln—p 101

Use of Blood Serum in Pregnancy Tests—By following the technic of Brown (using blood instead of urine in pregnancy tests) Anderson made an error of diagnosis in two of a hundred cases. In both cases a negative diagnosis was made instead of a positive one, which was later proved by clinical observation and delivery of full term fetuses. In both instances the animal was examined at the end of the twenty-four hour interval and the ovaries were examined grossly. However, if microscopic sections of these ovaries had been made at the time, it is likely that a positive diagnosis would have been possible. Numerous tests were run on the blood of a patient with a hydatidiform mole which gave a positive reading. These tests were done over a period of weeks after the patient had expelled grapelike vesicles on numerous occasions. After curettement had been done and symptoms of the mole had disappeared, another test was run which gave a negative reaction. The patient has had no subsequent symptoms referable to a chorion epithelioma. The author emphasizes the point that the anterior pituitary hormone is more concentrated in the blood serum per unit of volume than in the urine, therefore that using blood serum instead of urine is more accurate, and that the modified technic of the Friedman test as described by Brown is practical, accurate and economical.

Infestation with Diphyllbothrium Latum—Ronka presents a case of Diphyllbothrium estum infection in which, though the patient harbored the fish tapeworm in her intestine, she suffered no ill effects from the parasite. She presented a variety of clinical manifestations without anemia. The functional disorders were referable to the alimentary tract. A familial tendency of parasitism was exhibited. Man contracts the infection on consuming insufficiently cooked flesh of infected fish. The worm proceeds to develop within the intestinal tract and matures in five or six weeks after exposure, at the end of which time eggs first appear in the feces.

Aplastic Anemia Following Treatment with Gold Sodium Thiosulphate—Dameshek reports the case of a woman presenting the typical lesions of lupus erythematosus who was given nineteen intravenous injections of gold sodium thiosulphate (totaling 17 Gm) within about five months. At about the time of the last injection, symptoms referable to anemia developed and shortly thereafter she presented the typical features of aplastic anemia. She was given sixteen transfusions of blood within a period of nine months but at no time did she show any signs of regenerative activity on the part of the bone marrow and finally died. Although there is no absolute evidence, it was believed that the drug was of etiologic significance.

The Pathogenesis of Osteodystrophies and Bone Tumors—Levin states that osteitis fibrosa and deformans appear to be morphologically and roentgenologically similar to osteoplastic metastatic carcinoma of the skeleton. Only 25 per cent of all cases of carcinoma of the stomach and 3 per cent of all cases of carcinoma of the uterus show metastases in the bones. The types of carcinoma that most frequently develop metastases in the bones are carcinoma of the breast, of the prostate and of the thyroid. In carcinoma of the prostate the greatest number show extensive osteoplasia and the patients may continue to live even for years with a well functioning skeleton. In carcinoma of the thyroid the predominance of osteoplasia or osteoporosis is encountered with about equal frequency. In carcinoma of the breast, cases with osteoporosis are more frequently observed, and even a beginning of osteoplasia soon changes into osteoporosis. The destruction of the normal bone tissue (osteoporosis) in skeletal metastasis is a purely local processes and must be a direct function of the group of cancer cells transported to the bone. This function is most probably chemical and is analogous to the condition found in osteomalacia. The difference between the osteoporosis in carcinoma and in osteodystrophy consists in the fact that in the latter condition the cells which act on the bone do it at a distance and may represent the function of the parathyroids or other endocrine glands. The reason for the prominence of osteoplasia in some forms of osteodystrophies and tumors of the bone and its absence in others must be looked for in the differences of the function of the endocellular metabolism whether it concerns endocrine action, nutritional deficiency or local action of cancer cells. One type of cancer cells or of endocrine organs may predominate in its destruction of the bone over the reparative power of the latter, while in other types of cells the reparative function of the bone tissue predominates. Osteoporosis (rachitic, carcinoma of the breast) prevails in the young and osteoplasia (Paget's disease, carcinoma of the prostate) predominates in old age. This coincides with the fact that during senescence many types of parenchymatous tissues are replaced by fibrous connective tissue. Scirrhus carcinoma, in which the fibrous stroma predominates is also a disease of old age. A final diagnosis of Paget's disease should not be made until the possibility of a primary malignant process elsewhere in the body is excluded. In the case reported by the author the mechanism of the healing of the traumatic fracture established the diagnosis of Paget's disease though the patient did not present a classic picture of the disease.

Tobacco Sensitivity in Peptic Ulcer—Ehrenfeld and Sturtevant gave injections of tobacco protein to fifty-five patients, proved roentgenologically to be suffering from peptic ulcer, in order to determine whether tobacco had any effect on gastric function. Only two patients gave a marked, characteristic positive reaction to the three antigens that were used, and nine reacted to a concentrated mixed tobacco solution with a slight increase in the size of the wheal and a faint zone of erythema but no pseudopodia. These reactions were considered negative. Passive transfer was attempted from the two positive reactions to four persons, giving negative results in the eight instances.

*Effect of Ferric Chloride Injections in Experimental Tuberculosis V Menkin Boston—p 211
Frogs and Opalimidae M M Metcalf Waban, Mass—p 213

Rapid Method for Preparing Delafield's Hematoxylin—Neild reduces the ripening period of Delafield's hematoxylin from sixty days to three hours by preparing the solution in the usual way and placing it in an open dish, at a distance of 15 cm from a Cooper Hewitt burner, operating at 140 volts and 33 amperes, for one hour. The solution is then filtered and 100 cc of methyl alcohol and 100 cc of glycerin is added to it. This solution is placed under the Cooper Hewitt burner at the same distance for two hours. The solution is then filtered and used for staining purposes. The author noticed no appreciable difference between the staining quality of the hematoxylin prepared in this manner and that left for sixty days to ripen.

Effect of Ferric Chloride Injections in Tuberculosis—Menkin inoculated intravenously ten rabbits each with 0005 mg of a relatively avirulent strain of bovine tubercle bacilli. Six weeks later each one of these ten rabbits was inoculated subcutaneously in the thigh with 005 mg of a virulent bovine Ravenel strain of tubercle bacilli. Repeated intravenous injections with a 0.25 per cent solution of ferric chloride were immediately started in five of the rabbits, the remaining tuberculous animals were kept as controls. The ferric chloride injections were carried on for about fifteen weeks and then discontinued. The first control rabbit died forty-seven days after reinfection with tubercle bacilli. The last of the control rabbits died 130 days after reinoculation with the bacilli. At necropsy these control animals displayed widespread confluent tuberculous lesions affecting primarily the lungs, with discrete tubercles in the kidneys, and with prominent tuberculous abscesses at the site of subcutaneous reinoculation. The first experimental rabbit died eighty-one days after reinoculation the second 110 days later and the third 131 days after reinfection with tubercle bacilli. Two of these three animals had an infection of the upper respiratory tract at the time of death. All three rabbits showed discrete caseous tubercles in the

lungs, with hardly any confluence of lesions. The two remaining animals continued to increase in weight for more than six months after the death of the last control, and 334 days after reinoculation with tubercle bacilli these two rabbits were killed. One showed absolutely no sign of any lesion in the thigh. The other rabbit, which had just begun to show a slight loss in weight at the time it was killed, presented a somewhat more tuberculous involvement at necropsy.

- *Operative Treatment of Infantile Hydrocephalus R G Doughty, Columbia—p 51
Modern Open Method of Treating Certain Fractures J H Taylor, Columbia—p 54
Ludwig's Angina Report of Cases D St P Ashill, Columbia—p 55

Operative Treatment of Infantile Hydrocephalus—Doughty states that in infantile hydrocephalus, if after intraspinal injection of the phenolsulphonphthalein none of the dye is obtained from the ventricle and only a 10 per cent output is shown from the kidney, one is dealing with a block of the ventricular system and an absence of the arachnoid and there is no operative procedure worth while. If, however, no dye is obtained from the ventricle and the two hour phenolsulphonphthalein output approximates 40 per cent, there is not only a block present but the arachnoid is present also and is functioning, and a third ventriculostomy offers considerable hope. The author reports a case of hydrocephalus in a child of 4 months in whom a lumbar puncture was done and, following the removal of 1 cc of spinal fluid, 1 cc of phenolsulphonphthalein was injected. Twenty minutes later a tap of the left ventricle failed to show any dye in the fluid obtained. During the two hours subsequent to the injection of the phenolsulphonphthalein the urinary output was extremely small and only a 12 to 15 per cent phenolsulphonphthalein return was obtained. Subsequently this was repeated, and while the urinary output was again small there was a return of 30 per cent of the phenolsulphonphthalein in two hours. The head was put in a plaster cast and, through a curved left temporal incision, the brain was exposed. The left lateral ventricle was tapped and partially emptied. The temporal lobe was then lifted up and the bulging arachnoid at the base was torn. The wall of the lateral ventricle was then quite prominent. It was widely incised just posterior and lateral to the hypophyseal stalk. The cavity was then filled with physiologic solution of sodium chloride, the dura and temporal bone were sutured and the galea and skin were closed. The baby's general condition was fair. For about a week after operation the child's temperature ranged from 101 to 105 F, but he was conscious and took his feedings well. Following this the temperature gradually returned to normal. There was a slight skin infection in the wound, which cleared up quite readily. The cast was removed three days after operation. On dismissal from the hospital, two weeks after operation, the fontanels were soft and fluctuant and the circumference of the head was less than 20 inches. The patient has continued to improve, the fontanel has remained soft and the circumference of the head, six weeks after operation, was 19 inches.

*Mite Infestation in the Human Intestine R H Kampmeier and E H Hinman, New Orleans—p 271

Mite Infestation in the Human Intestine—Kampmeier and Hinman present two cases of gastro-intestinal mite infestation. Diarrhea was the chief presenting symptom and ceased on elimination of contaminated food from the diet. It was possible to correlate proctoscopic and pathologic observations in one of these cases, owing to intercurrent pneumonia and death. The source of the ingested mites could not be ascertained, but the social stratum of the patients made mite contamination of food probable. Chronic diarrhea is probably due to continuous reinfestation as a result of constantly eating contaminated food. The organisms probably have only a temporary sojourn in the intestine, especially when diarrhea is present. Oviposition and hatching of eggs unquestionably occur, but completion of the life cycle seems doubtful. Treatment would appear to consist only of the elimination of food contamination. The incidence of intestinal mite infestation would be difficult to determine. Routine fecal examination would undoubtedly fail to reveal many cases. The eggs, if observed, might be mistaken for those of the hookworm or other nematodes. Since only a few eggs are deposited daily, they may be readily overlooked. Culture of stools obtained with adequate precaution is the most reliable method of diagnosis. Failure to find the parasites does not exclude the possibility of their presence. Unclean catheters and douche tips when used by the public or others may be the sources of contamination in such cases.

Vaginal Approach to Peritoneal Cavity—Babcock points out that in the adult woman the lower peritoneal cavity may be entered, explored and drained in the simplest and quickest way through the vaginal vault. Here the extraperitoneal layers are only a few millimeters in thickness and the peritoneum may be entered by a single thrust of a pair of curved scissors. Such an opening may be readily enlarged by the fingers alone to a size sufficient for exploration of the pelvis and lower part of the abdomen without the division of a single important blood vessel or the need of a ligature. Not infrequently a hand may be introduced through such an opening and the lower abdominal structures may be palpated. At the completion of the operation no sutures or peritoneal closure is required; a gauze drain laid through the opening completes the operation. Secondary complications resulting from the vaginal approach are rare, as the integrity of the anterior abdominal wall is not jeopardized. If skillfully done, the vaginoperitoneal section is usually much safer and has a lower mortality than an abdominal section. Against the manifest advantages for the patient, the surgeon must contend against increased difficulties, restricted operative field, special instruments and methods of illumination. Adequate training to avoid injury to intestine, bladder, ureter or other important structure and to ensure dependable hemostasis is essential.

Diabetes Insipidus Associated with Pinealoma—Stringer presents the history and necropsy observations of a man, aged 27, who suffered from diabetes insipidus for a period of five months preceding death, which followed after a period of hyperpnea of 107 F lasting one week. Generalized signs of an intracranial tumor were absent. The administration of solution of pituitary was at first successful in relieving the diabetes insipidus, but gradually this therapeutic measure failed to be effective. At necropsy a pinealoma was found in the pineal body and a transplant of this tumor was present in the region of the tuber cinereum. This metastatic implant destroyed the tuberal group of hypothalamic nuclei and invaded the stalk of the hypophysis producing closure of the infundibular canal.

*Diagnosis of Renal Tuberculosis by Cultures Made from Urinary Sediment D N Esendrath—p 37

Diagnosis of Renal Tuberculosis by Cultures—Eisendrath says there is a close relation between the elimination of tubercle bacilli from a tuberculous kidney and the anatomic changes incident to such an infection. For this reason one may find the bacilli at one examination and not at another. In the author's first series, consisting of fifty-seven cases, the cultures were positive in thirty, whereas the stain was positive in only twenty of the thirty. In a second series, of thirteen cases, the culture was positive in seven, whereas the stain was negative in the five but had been positive at previous examinations in four of the five cases. The bladder specimen may be negative and that taken directly from the kidney may be positive, hence it is always advisable to examine the urine obtained by ureteral catheterization. The author is of the opinion that one should always control the culture by animal inoculation to avoid error. One should keep the cultures under observation for at least ninety days. The culture method should be employed as a routine measure whenever the stain is negative. The chief advantage of making a smear before visible colonies appear is that one can find the bacilli as early as the seventh day, whereas the earliest visible colonies were not found until the fourteenth day. That tubercle bacilli may be found in the urine by culture from three to ten years after nephrectomy was evident in five of the author's cases.

*Leaking Cerebral Aneurysm G D Kersley—p 376

Leaking Cerebral Aneurysm—Kersley presents the case of a multipara, aged 38 sent to the hospital because of antepartum hemorrhage. Six months previously she had experienced a sudden intense occipital headache, which gradually subsided. There was albuminuria and a blood pressure of 215 systolic, 140 diastolic. There were no labor pains, but the cervix was three fingers dilated, the placenta could not be felt. The following night the patient fainted, labor pains began and there was a profuse hemorrhage from the uterus. The membranes were ruptured and a stillborn child was delivered. The mother collapsed, with a pulse rate of 130 and a blood pressure of 140. Two hours later she had a fit, lasting six minutes, with opisthotonos and clonic movements of the limbs. Under treatment with morphine and chloral she improved a little but remained somewhat cyanosed. On the fourth day the temperature rose to 101 F, the breasts became tender and the patient became more lethargic. The blood pressure was now 180. On the sixth day after delivery the patient developed a right hemiplegia. The diagnosis of leaking aneurysm was confirmed by lumbar puncture, when the cerebrospinal fluid was found to be intimately mixed with blood, with a colored supernatant fluid after centrifugation. The patient gradually became more comatose and died on the tenth day. At necropsy a small ruptured aneurysm was found at the origin of the left middle cerebral artery, and another aneurysm, about 3 mm

in diameter, was situated close by on the posterior communicating artery. It seems likely that six months previously the patient had a slight leak from an aneurysm, in the latter months of pregnancy she became toxemic and finally had an eclamptic fit, which caused the aneurysm to leak again, with a fatal result.

Carbon Dioxide Therapy in Lobar Pneumonia—To determine the value of carbon dioxide in lobar pneumonia, Hilton took a sample of blood from the femoral artery, administered approximately 3 per cent carbon dioxide with a loose face mask and made examinations of the breathing and the blood fifteen minutes later. The blood gases were determined by the van Slyke method. To obtain these measurements he used a specially devised low resistance mask, which has proved its value in collection of air in dyspnea. He observed that arterial anoxemia is not relieved after carbon dioxide administration in these quantities in spite of the fact that the depth of the tidal air is considerably increased. He discusses the part that shallow breathing may play in the production of anoxemia, the action of carbon dioxide on the oxygen dissociation curve and on arterial carbon dioxide pain, blood pressure and cyanosis and concludes that in the absence of respiratory failure, as evidenced by shallow breathing, the clinical benefits of carbon dioxide administration in air are not sufficiently demonstrated to warrant its routine use in lobar pneumonia.

Treatment of Hypochromic Anemia with Ferrous Salts—Fullerton treated twenty-one cases of hypochromic anemia with small doses of ferrous sulphate (9 grains [0.6 Gm.] daily). Most of the cases were treated as outpatients. Ten patients (48 per cent) showed an average daily hemoglobin increase of 1 per cent or more and accordingly can be regarded as having responded satisfactorily to this form of therapy. Three patients showed a good response although falling short of the standard rise of 1 per cent hemoglobin a day. The remaining eight cases were complicated by hemorrhage during treatment. A comparison of the efficacy of iron preparations in the treatment of hypochromic anemia has shown that ferrous sulphate treatment appears to be reliable when hemoglobin deficiency is the essential feature and that the speed of its return to normal is surely the best index of therapeutic efficiency.

Bacilli in Blood in Tuberculosis—Emslie made fifty-four blood cultures by Loewenstein's technique and twenty-eight animal inoculation tests (omitting the two animals that died within two weeks) for tubercle bacilli with the blood of thirty-four known tuberculous and four nontuberculous patients, and

in two cases some result other than a definite negative has been found. Two cases produced acid-fast bacilli which failed to infect guinea-pigs. As both subculture and animal inoculation with scrapings of the cultures showing acid-fast bacilli failed, it is impossible to regard them as tubercle bacilli. All animal inoculation tests were negative. Reexamination at a later date of the cultures containing acid-fast bacilli revealed that they had disappeared from the culture. The author concludes that the occurrence of any degree of continuous tuberculous bacillæmia is not proved. Acid-fast bacilli are to be found in the cultures by various methods the proportion varying with the different investigators. The author obtained a percentage of 53 by his method. The exact nature and source of these acid-fast organisms have not yet been determined, but it is highly probable that they are contaminations from sources such as glassware and tap water. Loewenstein's results have not been confirmed by the author, whose work agrees with the observations of Schwabacher, Weatherhall, Cummings and Pearce. Loewenstein's medium is suitable for the culture of tubercle bacilli.

*Investigation into Relative Immunizing Value of Kasauli and Paris Strains of Rabies Fixed Virus H E Shortt R H Malone, A C Craighead and J P McGuire—p 1

Kasauli and Paris Strains of Rabies Virus—As the result of human inoculations carried out in a series of 15,910 cases, Shortt and his associates demonstrate that the Paris strain of rabies fixed virus is superior in immunizing properties to the Kasauli strain of rabies fixed virus. An extensive series of animal experiments confirms this conclusion. The minimal lethal dose of the Paris strain of rabies fixed virus is smaller than that of the Kasauli strain, but the latter kills animals in a shorter time, averaging about twenty-four hours less. In the experiments devised for testing the relative immunizing values in human cases of these two strains and in the interpretation of the results of the experiments, homogeneity of the treated population during the entire time range of the experiments, the uncertainty as to the number of persons actually at risk, the plurality of street viruses, the species of the biting animal and the uniformity in the classification of the cases were taken into consideration.

*Secondary Thiersch Grafting of Radical Mastoid Cavity Through the Meatus W I Daggett and G H Bateman—p 169

Grafting of Mastoid Cavity Through the Meatus—Daggett and Bateman believe that the logical solution in mastoid cavity grafting is through the meatus at the end of a fortnight. They operate with especial attention to refashioning a wide meatus, under gas, changing the dressing on the seventh day from the seventh to the fourteenth day the dressings are changed and the cavity is syringed when necessary, on the fourteenth day the cavity is grafted under a barbituric acid derivative (evipan) anesthesia and wax is poured in, on the fifteenth or sixteenth day the patient leaves the hospital the top dressing is changed when necessary till the twenty-eighth day, on the twenty-eighth day the wax is removed and powder is insufflated and the cavity is inspected periodically as circumstances dictate. In the nineteen cases in which the foregoing method was employed, the grafts have taken and there has not been a single instance of adhesion between the roof and the facial ridge. In six the cavity has remained completely dry from the time the wax was removed. In one patient having complete facial paralysis before operation the facial movements were normal a week after removal of the wax and only a small moist area persisted over the site of the fistula.

Treatment of Puerperal Infection—Colebrook and Hare give the results obtained in the treatment of sixty-six cases of puerperal infection by *Streptococcus pyogenes* with organic arsenical compounds (usually of the sulpharsphenamine type). In twenty-nine cases in which, when treatment was commenced, the infection was limited to the tissues of the genital tract, the spread of the streptococcus invasion beyond those tissues occurred much less frequently (in 31 per cent as compared with 47) than in a control group of approximately similar cases. *Streptococcus pyogenes* did not disappear from the lochia during treatment by arsenicals. The arsenical content of the lochia in several cases following administration of arsenicals was usually low, suggesting that the transudate from the blood vessels into the infected tissues of the body of the uterus was too small to allow of any considerable destructive effect on the streptococci in that situation. In a group of twenty-eight cases presenting an infection of the blood stream (positive blood culture) in which peritonitis could be excluded there were three cases in which it appeared probable that the treatment had had a definite effect. The rate of recovery for the whole series, however, was only 40 per cent as compared with 42 per cent for a control group of similar cases treated by various other methods. In most of the patients whose blood yielded more than one or two colonies per cubic centimeter of blood before the arsenical compound was administered, negative blood cultures were not obtained during the treatment. Necropsies on several of the treated cases indicated that the probable reason for failure was the presence of septic clots in large pelvic or abdominal veins into which a bactericidal agent could not be expected to penetrate. In a group of nine cases of general peritonitis (four giving a positive blood culture) there was no apparent effect of treatment.

Heredity and Diabetes Mellitus—From a study of 800 cases of diabetes reported previously, in 224 of which there was a history of glycosuria in blood relations and his present report of 1000 cases in 396 of which there was a history of familial diabetes, Cammidge states that the available evidence confirms the dictum of Naunyn that the more carefully the family histories are inquired into, the more frequently is evidence of heredity discovered. At present one can safely say only that heredity is a factor in the etiology which has to be reckoned with much more seriously than has been supposed previously. Seeing that the potentiality for developing diabetes may be transmitted either as a mendelian recessive character or as a mendelian dominant, it is necessary if the part played by heredity is to be fully determined, that the investigation of the histories of diabetic patients should include all blood relations, that is to say all persons related by blood and not merely by marriage as far as possible and not be confined, as it often has been in the past merely to immediate members of the family for as is well known a recessive character may remain in abeyance for several generations and be evident only in collaterals. Differentiation of the recessive from the dominant type is of some clinical importance

since the dominant variety is almost invariably mild and is easily controlled by diet alone, it usually persists for many years, even in young people, without causing serious symptoms or materially affecting the general health the recessive form, on the other hand, is generally grave from the onset and almost invariably requires the use of insulin to keep it under control.

Esophageal Obstruction R M Glynn—p 329
*Reactions Produced by Hydncarpates in Chronic Pulmonary Tuberculosis L W Martin—p 334
Vitamin C G Bourne—p 339

Hydncarpates in Chronic Pulmonary Tuberculosis—Martin states that in vitro experiments show the hydncarpates to have a definite bactericidal effect on tubercle bacilli. Cummins has shown that sodium hydncarpate (alepol) in a dilution of 1 1,000,000 only has a growth-inhibiting and probably bactericidal effect on tubercle bacilli growing in Besredka egg medium. Other workers have found hydncarpates in a dilution of from 1 100,000 to 1 1,000,000 to inhibit the growth of avian tubercle bacilli. Favorable results have been obtained in surgical tuberculosis. The author employed subcutaneous injections of hydncarpates in chronic pulmonary tuberculosis in six selected cases, using a sterile 2 per cent solution with 0.5 per cent phenol acid. In none of the cases were immediate or late beneficial results obtained. The effect of injections was to produce undesirable pulmonary reactions and a temporary setback to any improvement that was occurring under general hygienic measures. Though only small doses were given, it was thought that the continuation of treatment would be detrimental to the patients concerned. Topical applications of sodium hydncarpate to tuberculous ulcerations of the larynx had no effect in relieving pain or checking ulceration.

Treatment of *Schistosomiasis Japonica* with Fuadin—Lee and Chung treated four cases of *schistosomiasis japonica* with fuadin. One patient derived no apparent benefit from the treatment. In the other three, clinical improvement with disappearance of eggs from the stool followed the treatment, but relapse occurred in all after a time. Any possibility of reinfection was excluded by virtue of the patients continued residence in a nonendemic area during the period of observation. As compared with antimony and potassium tartrate, fuadin is less toxic and more easily administered. One of the patients, however, showed marked sensitivity to it, and the treatment had to be discontinued. For the present it does not seem safe to regard fuadin as a reliable specific in bringing about a permanent cure in *schistosomiasis japonica*.

Sweating in Angina Pectoris—It has been recognized for years that attacks of profuse sweating may alternate in certain persons with attacks of anginal pain Urioste and Blanco cite four patients of advanced age in whom periods of profuse sweating occurred In all instances cardiovascular disease was present and had been producing other symptoms, or these developed later The sweating crises were characteristically abundant and generalized, or predominant in the anterior portion of the neck and thorax They were always accompanied by pallor, peripheral chilliness, tachycardia and a sensation of distress or even a sensation of approaching death They might follow effort, digestion and emotion, or arise during nocturnal rest If the sweating occurred in elderly people before any other sign of serious cardiovascular disease, it announced the serious nature of the condition The authors look on these crises of sweating as a defense reaction of a viscerosensory-motor reflex substitute for typical anginal attacks They must, however, be considered to have the prognostic significance of atypical angina

Gaseous Distention of Retrosternal Pleural Pouch in Therapeutic Pneumothorax—Grandgerard and Weber state that mediastinal hernia occurring during artificial pneumothorax causes symptoms of dyspnea, pain and cardiac disturbance To relieve the patient, the pneumothorax cavity should be aspirated and the pneumothorax carefully continued with refills of smaller amounts under reduced pressure and at longer intervals There are two weak spots in the mediastinum, the upper lying between the first and third ribs anteriorly and the lower between the fifth and tenth dorsal spines posteriorly In most cases hernia occurs in the upper and anterior mediastinal weak spot Hernia has been observed in the presence of highly positive intrapleural pressure and of definitely negative intrapleural pressure The authors maintain that the lung will collapse satisfactorily only when the air is introduced at a pressure higher than the atmospheric pressure This pressure, which is distributed through the whole pleural cavity, allows distention to occur at the weakest spot This distention appears soon after filling If filling is done in the pleural cavity where the retrosternal pouch overlaps the opposite side, distention appears rapidly In typical cases the leaves of the mediastinal pleura are directed obliquely from front to back and from left to right, the left pouch projects beyond the right anteriorly If the patient receives insufflations into the left pleural cavity, the left pouch reacts to pressure by forcing it back, the distal end finds its way between the thoracic wall and the costal pleura of the opposite side, slips and, separating the costal pleura, projects into the contralateral half of the thorax In a number of cases the authors constantly found a positive pressure in the hernial sac as well as in the principal pleural cavity Distention of the retrosternal pouch was found only in young patients aged from 18 to 31, their age favoring a flexible mediastinum In these young patients the pleura is rarely the seat of pathologic disturbances such as pachypleuritis and adhesions found in older patients The authors emphasize the importance of the

anatomic predisposition of the sternomediastinal pleural leaves for the formation of a distention of the retrosternal pouch Although this complication is usually harmless and does not hinder the course of the pneumothorax, it is necessary to know how to administer the injections in such a way as to reduce the hernial pouch or at least to arrest its progress

Subcutaneous Vaccination with Neurovaccine—Gallardo feels that subcutaneous vaccination with the neurovaccine of Levaditi may advantageously replace dermal vaccination The technic is simple and serious complications are not encountered Positive results in children more than 4 months of age and in the revaccinated are comparable to those obtained by the dermal method Local manifestations always appear more slowly than in dermal vaccination It appears that immunity produced by subcutaneous vaccination is just as effective as that by dermal The patients with negative reaction to subcutaneous vaccination could be divided into two groups In forty-three nurslings (ten less than 4 months of age) a second cutaneous inoculation was performed at the end of twenty or thirty days In twenty of these the reaction was positive, in nine an allergic type of reaction occurred and in fourteen there was no reaction Thirty-four children more than 4 months of age formed the second group These were given a second subcutaneous dose of vaccine thirty days after the first In ten the results were positive The twenty-four having negative results were revaccinated by scarification, four of these showed typical pustules of slight intensity, four others an allergic reaction, and sixteen no reaction The author believes that subcutaneous vaccination with neurovaccine has a good future and further experiments may modify the technic toward obtaining a perfect immunization with a minimum of reaction

- Anesthesia with Tribrom Ethanol in Children H L Rocher and J Souillard—p 803
- *Chorea and Rheumatism N Faven—p 809

Syphilitic Etiology of Infantile Diabetes—Mikulowski admits no doubt that congenital syphilis may produce diabetes Examination of the curve of sugar content of the blood in eighty children having congenital syphilis revealed a definite tendency to pathologic hyperglycemia Although the classic signs of congenital syphilis are often lacking in infantile diabetes, critical study shows a series of analogies between the two pathologic entities Thus in infantile diabetes the existence of congenital malformations and anomalies is a frequent and characteristic sign Similar observations are frequent in syphilitic children A comparable analogy lies in the neuro-pathologies and convulsive seizures in both syphilitic and diabetic infants Anatomic and physiologic studies of diabetes demonstrate the existence of syphilitic lesions of the pancreas or liver Evidence based on the specific effect of antisiphilitic treatment of infantile diabetes is uncertain and inconclusive, perhaps because of the sclerotic nature of the lesions in the pancreas, or because of the more important and pressing part played by insulin

Chorea and Rheumatism—Faven studied 117 cases of Sydenham's chorea, 84 girls and 33 boys In 91 cases the condition developed between the ages of 7 and 13 In 70 (60 per cent) a definite relationship to rheumatic infection was demonstrated, but the clinical course of cases without other rheumatic manifestations was similar to that of cases with

cardiac or articular symptoms. The majority of the cases of chorea developed during the cold season (from November to April). The small number of cases, however, does not allow a satisfactory statistical study. Study of these patients with the sedimentation reaction showed a normal rate in cases of uncomplicated chorea. This agrees with the observation of most other investigators. Usually the sedimentation rate increased with the advent of infection or endocarditis, but sometimes, in spite of complications, the rate remained normal.

Best Technical Conditions for Cultures in Anaerobiosis B Trambusti—p 23

Differentiating Between *Pasteurella* and the *Bacillus Coli-Paratyphoid* Group—Pagnini adds two or three drops of Loeffler's methylene blue to an average test tube containing from 7 to 8 cc of common broth. He found that *Pasteurella* when placed in the tube does not discolor the culture medium even after being several days in an incubator at 30 C. At most, some strains of *Pasteurella* give the medium a weak greenish tinge. The *B coli-paratyphoid* group begins to discolor the culture medium a few hours after it has been introduced into it, after twenty-four hours, discoloration is almost complete and the medium turns a bright green. This difference in behavior of the two groups of micro-organisms is clearly manifested in twenty-four hours and often evinced after from eight to ten hours. The author observed that *Pasteurella* refrains not only from discoloring the medium but also from rendering it turbid, whereas the bacilli of the *coli-paratyphoid* group always produce discoloration and turbidity of the culture medium. Thus Loeffler's methylene blue when added to the broth does not hinder the development of the *B coli-paratyphoid* group but greatly inhibits that of *Pasteurella*. This inhibitory action on *Pasteurella* may also be observed when Loeffler's methylene blue is added to a simple agar medium.

Narcosis with Evipan Sodium V Podetti—p 616

Symptoms of Awakening from Ether Anesthesia—Faenza studied 100 operative patients to whom general ether anesthesia had been administered. In forty-four the symptom of awakening was represented by lateral movements of the eyeball, in fourteen by lateral nystagmus, in thirteen by groaning in seven by vomiting, in six by return of the pupillary reflex to light, in three by return of the corneal reflex in two by lateral and vertical nystagmus, in one by temporary lateral nystagmus and groaning, and in nine, in addition to lateral movement of the eyeballs, there was a corneal reflex in one, lateral nystagmus in three, vomiting in two, groaning in two and a pupillary reflex to light in one. The author concludes that the period of awakening in general ether anesthesia is not marked by the return of the corneal reflex in the majority of cases but by lateral movements of the eyeballs.

Mueller's Conglobation Reaction for Diagnosing Syphilis—Santone tested 1,187 serums and 201 specimens of cerebrospinal fluid with Mueller's second conglobation reaction and with the Wassermann reaction. He found that in serums Mueller's reaction is 133 per cent more sensitive and 104 per cent less specific than the Wassermann reaction. In cerebrospinal fluid Mueller's reaction was less sensitive than the Wassermann reaction but not to the degree at which it ever gave any nonspecific results. The Wassermann reaction was absolutely specific never having given positive results in non-

syphilitic fluids. In no case did Mueller's reaction show itself thermolabile, whereas the Wassermann reaction manifested its thermolability in several cases. The author states that Mueller's reaction must be considered one of the most valuable sero-diagnostic methods for the determination of syphilis and as such merits adoption in the laboratory as a concomitant test to the Wassermann reaction.

Leotta's Sign of Perivisceral Adhesions—Rabboni attempted to establish the existence of adhesions in the upper quadrant between the colon and the liver or gallbladder according to Leotta, in 100 patients presenting a right abdominal syndrome. Leotta's maneuver consists in placing the hand on the right abdominal quadrant and exerting a downward pressure with the fingers. The traction, because of a downward pull exerted on the colon below, is painful if the colon is adherent to the gallbladder or liver. The pain becomes more marked if the patient is asked at the same time to expire forcibly, causing the diaphragm to rise and to displace the liver and gallbladder upward. To establish the existence of adhesions between the ascending colon and the parietal peritoneum, the maneuver of stretching is applied to the inner part of the right half of the abdomen by making traction with the hand in a transverse direction and from the lateral aspect toward the median line. Thus, if adhesions exist between the ascending colon and the parietal peritoneum, stretching will elicit a sharp pain. The author found this sign positive in 74 per cent of patients presenting the simple right abdominal syndrome and in 100 per cent of patients whose right abdominal syndrome was complicated by gastroduodenal ulcer and cholecystitis. The validity of this test was proved at operations by establishing the presence of adhesions and their topographic localization corresponding to the direction of stretching necessary to bring out the pain. When the sign was negative, few adhesions were found and these for the most part were localized about the cecum, appendix and ileum.

*Weltmann Coagulation Test in Pleurisy R D'Alessandro—p 523

To Diminish Risks of Postoperative Gastric Hemorrhage G Cavina—p 530

Echinococcosis of Muscles of Lumbar Region Case B Picardi—p 533

Weltmann Coagulation Test in Pleurisy—D'Alessandro applied the serocoagulation test of Weltmann to thirty patients with pleurisy. He noticed during the exudative stage a diminution of the coagulation band or a deviation to the left, and during the stage of absorption and fibrosis a widening of the band or a deviation to the right. In two cases the deviation to the left concurred with specific lesions of the homolateral lung and of the contralateral lung and was manifested as a pleurisy due to an osseous tuberculous lesion. In exudative cases of dry pleurisy presenting symptoms of fibrosis, the coagulation band always deviates to the right, especially when the disease is regressing. In pleural diseases with fibrous involvement the widening of the coagulation band may be dependent on modifications in the protein fractions of the blood serum. The deviation of the coagulation band toward the more diluted solutions may concur with an increase in the seroproteins of this fraction at a lower electrolytic threshold. It is best to increase the more diluted solutions of calcium chloride in order to bring about coagulation. The deviation of the coagulation band to the left or to the more concentrated solutions demonstrates a diminution in the coagulability of the serum; this is observed in inflammatory exudative processes in which the cellular disintegration is more intense and the protein content therefore greater. The author states that the serocoagulation reaction of Weltmann in patients presenting pleurisy and other diseases has a practical prognostic and diagnostic value. The deviation to the right when the pleural liquid is absorbed is valuable in that it indicates another pleural

process not easily revealed by symptomatologic examination and calls attention to the development of a tuberculous process of the lung

 Nongonococcal Urethritis J. J. Gazzolo—p 517

Sign in Aneurysm of Left Auricle—Lorenzo describes under the name of Broadbent's inverted sign a new sign for the discovery of aneurysm of the left auricle. It consists of a localized pulsation in the lateral and posterior wall of the left hemithorax synchronous with the ventricular systole. The author reports a case in which he observed the sign and studies its pathogenesis. He believes that the auricle, greatly dilated, causes atelactasis of the lung and that its pulsations are transmitted through the lung and become perceptible to inspection and palpation on account of the impaired expansibility of the lung. The synchronism of the pulsation with the systole was due, in the author's case, to the existence of mitral insufficiency, which established a permanent communication between the ventricle and the aneurysmatic auricle. The author studies also the osseous propagation of the systolic murmurs and their displacement toward the right side. He describes the typical roentgenogram of aneurysm of the left auricle and makes especial reference to the double arch of synchronous pulsation given by the right outline of the roentgen image. He points out the advantages of the orthodiagram over the teleroentgenogram, especially because in the latter the double arch cannot be distinguished.

Effects of Repeated Administration of Histamine—Klein and Mahler studied the gastric juice, urine, blood, alveolar air and saliva of patients who were given four or five successive histamine injections at intervals of forty-five minutes. Then, to gain a deeper insight into the effect of the repeated histamine injections on the acid-base economy, the histamine experiments were preceded by a period of salt-free diet, by intramuscular injections of merbaphen, or by either an acid or an alkaline diet. It was found that, in persons with hypersecretion, up to 4 Gm of chloride could be eliminated through the stomach in three and three-quarter hours. In patients with achylia, up to 25 Gm of chloride, mostly in the form of neutral chlorides, is eliminated under the same conditions. This shows that the secretion of neutral chlorides can be promoted by histamine stimulation even in cases in which free hydrochloric acid is lacking. The repeated histamine injections also frequently promote the renal secretion in the absence of fluid intake and simultaneously with the loss of fluid and chlorides through the stomach. In some persons the urinary secretion ceases rather early, while in others, particularly in achylic patients, the increased elimination of urine is so noticeable that it appears as if, in case of insufficient response of the gastric glands, the kidneys were stimulated instead. The stimulation of the renal secretion of chlorides is especially marked in persons in whom the chloride secretion through the stomach is high (hyperacidity). The fluid secretion, however, is different, in that the water elimination through the kidney is generally greatest in those persons in whom the fluid elimination through the gastric juice is slight (achylia) and vice versa. The pH of the urine increases (greater alkali-

linity of urine) in cases in which there is a great loss of gastric juice and of acid. This indicates that the kidney acts as a regulator of the acid-base economy. However, under extreme histamine action this regulatory function may become exhausted. The blood chlorides show a decrease, particularly in patients with hyperacidity, and the alkali reserve of these persons frequently increases. In patients with achylia there are no such changes. The carbon dioxide tension increases correspondingly to the loss of acids. In a few cases the prolonged histamine stimulus caused a disturbance in this regulation on the part of the lungs. The injection of merbaphen and the salt-free diet changed the reaction of the organism to the repeated histamine injections in that the urine and the gastric juice revealed the loss in chlorides, and there are also changes indicative of the alkalization of the organism by merbaphen: greater rise of the alkali reserve and of the carbon dioxide tension of the alveolar air, and percental increase in the neutral chlorides. The dietetic and medicinal modification of the acid-base economy changed the effects of the histamine action only slightly.

Mucin Therapy of Gastric Ulcer—Henning and Norpoth employed mucin preparations in the treatment of gastric ulcers over a period of eighteen months. The favorable results induced them to study the action mechanism of the mucin. In summarizing, they state that: 1 Gastric mucin swells in water, in tenth normal sodium hydroxide and in tenth normal hydrochloric acid. 2 Mucin binds the hydrochloric acid partly by water combination and partly chemically by acid combination, which can be demonstrated in vitro and in vivo. 3 A certain amount of mucin becomes dissolved in the process of swelling in water, hydrochloric acid or sodium hydroxide, for it can be demonstrated by the determination of the protein content. 4 The viscosities of gastric juice, of hydrochloric acid of sodium hydroxide and of water are increased in various degrees by the admixture of mucin, the highest values being obtained in gastric juice and in hydrochloric acid. 5 There was no histamine or pepsin in the examined preparations. 6 Mucin inhibits the peptic protein digestion.

 *Important Reactions of Cerebrospinal Fluid for Demonstration of Meningitis and Description of New Method J. Geldrich—p 472
 Parenteral Calcium Therapy F. Schierenberg and H. Theisen—p 474

Cerebrospinal Fluid Tests in Meningitis—Geldrich emphasizes that there is no single cerebrospinal fluid reaction which alone is a reliable indicator of the presence of a meningitis, but that the demonstration of all characteristic changes is necessary for a definite diagnosis. He mentions, as the characteristic changes of the cerebrospinal fluid, increase in the protein content, in the number of cells and the lactic acid content and decrease in the sugar content. In connection with the protein content he reviews the Pandy test and the foam test of J. Pauncz, and for the determination of the increase in the number of cells he recommends the pus reaction of Walthner, which is really the Donne test applied to the cerebrospinal fluid. The demonstration of the reduction in the sugar content encounters certain difficulties, and for this reason the detection of an increase in the lactic acid content is of great importance. The lactic acid test is done according to Hopkins. Into a test tube with 5 cc of concentrated sulphuric acid and 1 drop of saturated cupric sulphate, the author puts 0.3 cc of cerebrospinal fluid. After shaking, the test tube is placed for from one and a half to two minutes in a boiling water bath and is cooled off under running water or in ice. Then 0.1 cc of an alcoholic solution of thiophene is added and the test tube placed once more in the hot water bath. After the tube has been shaken for from twenty to twenty-five seconds it is rapidly cooled off. Now the reaction is read: a pink to cherry-red is positive, that is, it indicates a considerable increase in the lactic acid, however, a brownish coloration is negative. A lactic acid content of less than 20 mg per hundred cubic

centimeters always gives a negative reaction, but if it exceeds 40 the reaction is positive. Thus the reaction is positive only if the lactic acid increase is as considerable as it is found almost exclusively in meningitis.

*Symptomatology and Therapy of Hemolytic Icterus During Childhood M. Grob —p. 163

Hemolytic Icterus During Childhood—Grob points out that the diagnosis of hemolytic icterus may give considerable difficulties in children, particularly during the so called crises. He thinks that the higher incidence of hemolytic crises during childhood is due to the fact that, because of the greater activity of the growing organism, the equilibrium between the erythropoiesis in the bone marrow and the disintegration of the erythrocytes is more frequently disturbed. The sudden onset of the hemolysis which leads to a crisis, not only causes an aggravation of the symptoms already present (icterus anemia enlargement of the spleen and so on) but also the appearance of a number of new symptoms, which make the symptomatology of the crises extremely manifold. According to the predominance of the one or the other symptom a differentiation can be made. The thermic crises are characterized by increases of temperature that frequently persist for long periods. During the crisis-free intervals the rectal temperatures are often considerably increased while the axillary temperatures are normal. The abdominal crises may simulate acute appendicitis. The hemolytic crises (in the narrower sense) frequently lead to severe anemia and to severe reactions of the bone marrow with elimination of young red cells and of white cells, so that the blood picture resembles that of leukemia. The author describes a number of cases. In one, the hemolytic icterus concurred with signs of a hemolytic diathesis (cutaneous hemorrhages, thrombopenia). Splenectomy was performed, and there followed such a tremendous increase in the blood platelets (four million) as never before has been reported. In a case of splenomegaly, the injection of epinephrine produced a 100 per cent increase in the number of blood platelets in the circulating blood. This points to a hitherto unknown function of the spleen, namely, that of being a depot organ of the blood platelets. Extirpation of the spleen was done in two cases and so far has been of lasting effect (one and a half and two years), there was even an increase in the resistance of the erythrocytes.

Specific Gravity of Human Beings—Rehn and Horsch describe a simple method for the determination of the specific gravity of human subjects. They use a bath tub with an especially constructed volumeter. The test should be made in the morning following evacuation of intestine and bladder. The nose is closed with a clamp and a tube is attached to the mouth. The latter permits inspiration and expiration while the person is entirely submerged. On command, the person expels the air and holds the breath in deep expiration and the volumeter is read. The reading may be repeated several times.

The specific gravity is computed from the values of deepest expiration after deduction of the nose clamp and the tube. The authors cite the specific gravities of several persons. In a healthy man, aged 24, with a weight of 65.5 Kg, they determined a volume of 61.3 liters and consequently a specific gravity of 1.06443. A woman with thyrotoxicosis had a specific gravity of 1.09471, while a woman with endogenic obesity had a specific gravity of 0.9538. In an asthenic patient who underwent surgical treatment for an abdominal hernia the specific gravity was determined several times. Disappearance of gastric disturbances, a better food intake and improvement in the general condition, was followed by a decrease in the specific gravity (from 1.079 to 1.049). The authors think that such comparative determinations in the same person will prove to be a valuable aid.

Trendelenburg's Symptom in Disorders of Hip and Pelvis—Following the description of a case of tabetic arthropathy, which had been erroneously diagnosed, Ludloff shows how he recognized the true nature of the condition by giving attention to Trendelenburg's symptom, which consists in the downward instead of an upward movement of the pelvis on the side of the nonsupported leg when the patient is standing on one leg. The author shows that the symptom not only is produced by an insufficiency of the median gluteal muscle, but may have several other causes. The concurrence of Trendelenburg's symptom with lordosis and luxation is indicative of congenital luxation of the hip. The concurrence of the first two in the absence of luxation indicates muscular dystrophy. Trendelenburg's syndrome alone without either lordosis or luxation indicates coxa vara. In congenital coxa vara, the Trendelenburg symptom is present and the hip joint is deformed but lordosis may be either present or absent. The concurrence of Trendelenburg's symptom and of destroyed hip joint in the absence of lordosis may indicate either tabetic arthropathy or healed tuberculous coxitis. If in case of Trendelenburg's symptom lordosis is absent, the hip joint is normal but the sacro iliac synchondrosis is impaired, there exists either a loosening of the pelvic ring by fracture, tuberculosis or malignant tumors. The detection of the Trendelenburg symptom together with the anamnesis will often permit a definite diagnosis of disorders of the hip joint and the pelvis, but these diagnoses should of course be verified by inspection and roentgen examination.

Treatment of Tetanus—At his clinic, in Marburg, Hempel adheres to the intravenous injection of large doses of antitoxin in combination with tribrom-ethanol anesthesia. This method was employed in five cases. The author describes the clinical history of a boy, aged 6, in whom the tetanus developed after an incubation period of ten days. Hospitalization was not done until three days after the onset of the symptoms of a severe, generalized tetanus. The prognosis seemed unfavorable. Tribrom-ethanol anesthesia was induced (0.08 Gm for each kilogram of body weight [20 Kg]). Immediately after anesthesia set in, the wound was excised, injections of tetanus serum were made around it and a sterile bandage was applied. In the course of fifteen days the patient received in all 52.7 Gm of tribrom ethanol (increased doses at the later injections, 0.1 and 0.125 for each kilogram of body weight). The total number of antitoxin units was 720,000. During the first four days 480,000 units was given intravenously, and during the subsequent days the other 240,000 units was administered intramuscularly. At the end of the treatment there was still a certain stiffness in the extremities and in the back. The walk was insecure and motor pareses existed in both legs, particularly in the region of the peroneus. These disturbances disappeared gradually and after forty-nine days the patient was discharged completely cured. Of the other four patients treated with this method at the author's clinic two died and two recovered. In those who died the incubation period was comparatively short, being four and six days, respectively.

Changes in Blood in Disturbances Caused by Poison Gas—Muntsch discusses the changes caused by the poison gases of the green cross (phosgene) group and by the yellow cross (mustard gas-dichlorethylsulphide) group. He describes animal experiments he conducted with phosgene. He observed that during the first half hour after intake of the phosgene the

hemoglobin content increases slightly. During the following three hours it remains about the same or even decreases slightly, but beginning with the fourth hour it increases rapidly and reaches a maximum before the end of twenty-four hours, then it gradually decreases, and at the end of seventy-two hours again has reached the normal level. The number of erythrocytes runs practically parallel with the hemoglobin content. The rapid increase of both the hemoglobin and the erythrocytes sets in when the symptoms of pulmonary edema become manifest, before that the increase is so slight that a differentiation from the normal is almost impossible, and for this reason the determination of the hemoglobin content and of the number of erythrocytes is of no value for the early diagnosis. In studying the leukocytes the author observed a lymphopenia, a deviation to the left, but he admits that for an early diagnosis the studies on the leukocytes are of little value because they require too much time. The changes resulting from the loss of plasma in cases of phosgene poisoning are of great significance. There is a considerable increase in the inspissation and in the viscosity and the coagulation is accelerated. Attention was given also to the sedimentation, and shortly after the poisoning it was found that the speed increased slightly. The author thinks that, although the sedimentation speed alone cannot serve as a basis for the diagnosis, it is nevertheless a valuable diagnostic aid in phosgene poisoning. He reports his studies on the hematic changes in poisoning with mustard gas (yellow cross), dichloroethylsulphide. He found that poisoning with vapors of mustard gas produces in the blood changes similar to and perhaps even more severe than those that develop when the fluid substance acts on the skin. The number of erythrocytes and the hemoglobin content decrease, a temporary neutrophilia is followed by a neutropenia, and a passing lymphopenia by a lymphocytosis. There also is an eosinopenia, special forms of granulocytes appear and the segmented nuclei tend to degenerate. The blood picture presents essentially the same three phases (neutrophilia, monocytosis, lymphocytosis) that characterize an infection (Schilling's biologic curve of leukocytes). The sedimentation speed always shows an increase, which as a rule becomes noticeable three or four hours after the poisoning. The author emphasizes that in gas poisoning the blood picture reveals dangers as well as a favorable course, and he hopes that these studies on the blood will form a basis for new therapeutic methods, at least for poisoning by mustard gas.

*Changes in Blood as Diagnostic Aid in Disturbances Caused by Poison Gas. O. Muntsch—p. 529

Exogenic Causal Factors in Diabetes Mellitus—Curschmann points out that the role of the exogenic factors in the etiology of diabetes mellitus is still in dispute. His opinions are based on more than 400 cases. He thinks that the assumption of a syphilitic etiology of diabetes mellitus has an uncertain basis. In regard to the causal significance of tuberculosis he says that in case of concurrence of the two disorders in his series of cases tuberculosis always was the primary and diabetes mellitus the secondary disease. He denies the etiologic significance of occupation, mode of living and race. He considers the abuse of alcohol of no particular etiologic significance but thinks that excessive use of tobacco may at least lead indirectly to diabetes by promoting the development of arteriosclerosis. Carbon monoxide poisoning occasionally may lead to diabetes mellitus. The author observed two such cases and in this connection he calls attention to the traumatic, particularly the neurotraumatic, etiology of diabetes mellitus. He thinks that cerebral physical traumas as well as psychic traumas should be recognized as possible eliciting factors of diabetes mellitus and that absolute rejection of a neurotraumatic pathogenesis is not justified.

Autovaginoscopy. E. Bergmann—p. 369

*Abnormal Digestive Substances as Cause of Inflammatory Periarthritic Changes. E. Freund and Eva Kolmer—p. 371

Blood Transfusions in Ulcerative Colitis—Sinek made careful studies on the efficacy of blood transfusion in various conditions and reaches the conclusion that in cases of ulcerative colitis blood transfusion can be recommended but that expectation should not run too high. He found that blood transfusion had no effect in sepsis and in endocarditis lenta and that its efficacy was not quite convincing in typhoid.

Digestive Substances in Inflammatory Periarthritic Changes—Freund and Kolmer decided to study in mice the influence of extracts from stools of patients with articular rheumatism. They describe the preparation of the extracts, of which from 0.4 to 0.6 cc was subcutaneously injected into mice. Controls were treated in the same manner with extracts of stools from normal persons. Whereas the mice injected with the latter extract showed practically no changes, those injected with stool extract from rheumatic patients showed a reduced mobility, namely, a dragging of the hind legs and often swelling on the knee joints. These changes persisted for several days but then subsided gradually. The experiments were made on stools from twenty-three rheumatic patients (sixty-seven mice) and on six stools from normal persons (fifteen mice). In six rheumatic patients the results were negative, but in these patients the rheumatism was not in an acute stage. The histologic pictures did not unequivocally represent the aspects of rheumatism, but the authors point out that this could hardly be expected from a single product of the digestive activity, and they think that the results might be different if the abnormal products of digestion could be made active for longer periods by introduction directly into the intestine. They plan further studies along this line.

Significance of Determination of Blood Protein in Dysentery During Childhood. E. von Frolich and B. von Gozsy—p. 352

*Newer Points of View in Medicinal Treatment of Epilepsy. E. von Lederer—p. 359

Albuminuria in Young Persons—To obtain an insight into the incidence of orthostatic albuminuria, Nowak gave especial attention to the examination of the urine in 4,500 persons aged from 14 to 17 years, who were examined for occupational fitness. He discovered albuminuria in 560, that is, in 12.4 per cent of the young people. Of these, 524, or 11.6 per cent, had orthostatic albuminuria and 36, or 0.8 per cent, had a chronic renal disorder. Of the 524 with orthostatic albuminuria, 248 had a noticeable lordosis but the other 276 had disorders that would, like lordosis, lead to circulatory disturbances of the kidney. This latter group presented aspects indicative of weakness in the muscular, connective, cartilaginous and bony tissues, greater susceptibility to catarrhal infections and conditions such as excessive growth in height, neuropathic predisposition, severe dental caries and pulmonary or otic disorders. The author shows in a number of cases how gradual may be the transition from anephritic to nephritic albuminuria.

Treatment of Epilepsy—Von Lederer says that in the pathogenesis of epilepsy two factors play a part: (1) the irritative epileptogenic noxa (congenital, hercdogenerative, traumatic, inflammatory or sclerotic changes, toxicoses, tumors and disturbances in the circulation of the blood and the cerebro-

spinal fluid) and (2) a reduced spasmodic threshold (increased spasmophilia). The latter factor may be predominating in hormonal disturbances (hormonic dysfunction, puberty, menopause), during early childhood, at the beginning and end of a sleeping period and after eating. The treatment may be aimed at one or the other of these factors, various surgical interventions for the removal of traumatic and inflammatory sequelae or of tumors for the first and various medicaments to increase the spasmodic threshold for the second factor. The author observed that the customary bromine-phenobarbital medication failed in many cases and he resorted to the use of vasodilatory hormone preparations, the so called circulatory hormones, that are obtained from striated muscles or from the pancreas. The trials with these hormones seem to indicate that the peripheral (cerebral) vascular spasm is one of the important irritative epileptogenic factors, and that whenever the sedatives do not bring the desired results the circulatory hormones should be tried. The fact that in some cases of epilepsy the circulatory hormones proved ineffective does not prove the theory erroneous but only shows that in these cases the vascular spasm is not the eliciting cause. He cites a case in which most likely an injury of the brain was the causal factor.

*Treatment of Wounds with Resin Ointment Muller Meernach—p 405

Prevention of Inferiority—Bonne stresses the role played by alcohol, nicotine and syphilis in the degeneration of the offspring. He realized the importance of these factors in the development of inferiority not only in the course of his long private practice (forty-seven years) but also in studies on approximately 1,000 criminals. He relates the histories of twenty families in which inferiors of various types, such as idiots, epileptic persons, problem children, deaf-mutes, children subject to convulsions, homosexuals and criminals appeared, and in which he was able to trace the degeneration to syphilis, to the addiction to alcohol and nicotine, or to the fact that the child was conceived at a time when one or both of the parents were under the influence of alcohol. Fatigue, starvation, anxiety and addiction to morphine, cocaine or other narcotics may likewise lead to a disturbance in the psychic equilibrium of a person or his offspring but the author ascribes the greatest influence to the three factors named. The theory that drunkenness as such is a manifestation of degeneration is rejected by him, although he admits that an inferior conceived during intoxication may likewise become a drunkard. He thinks that in most instances drunkenness is a psychic infection produced under the narcotic influence of alcohol. He gained the impression that an asocial disposition, an inclination to criminality and homosexuality are frequently the result of chronic abuse of tobacco. He shows that by reducing the addiction to alcohol and to tobacco the economic crisis has exerted a beneficial effect, in that the incidence of idiocy and of other inferiorities has noticeably decreased. He considers the sterilization of the inferiors a step in the right direction, but he emphasizes that the attention of the people must also be directed to the injurious effects that alcohol, nicotine, syphilis and so on may have on the health of the offspring.

Treatment of Wounds with Resin Ointment—Müller-Meernach first resorted to the use of resin during the war, when he ran out of balsam of Peru. He made an ointment of equal parts of resin from larch trees (*Terebinthina larcina*) and petrolatum and he found it highly effective in the treatment of wounds. Now, after almost twenty years experience with this ointment, he is convinced that this simple preparation

makes all other ointments for wound treatment superfluous, although he did not neglect to try the various products of the chemical industry that were put on the market in the course of the years. He applied the ointment to surgical wounds, to wounds caused by accidental injuries and to acute suppurating wounds and abscesses, following their surgical treatment. Moreover, he found that the ointment stimulated the formation of granulations in wounds that had a tendency to slow healing.

Prepared Dried M and N Test Serums—Eisler points out that normal human serums (iso-agglutinins) are not used for the detection of the M and N factors, but rather immune agglutinins obtained by treating rabbits with human corpuscles that contain the factor in question. The author calls attention to numerous difficulties encountered in the preparation of these agglutinins and states that, after the test serums have been prepared, there arises the problem of keeping them effective for longer periods. Since in the fluid state they can be preserved for only a comparatively short time, the author decided to dry them, and he found that, when this was done, they were still effective after storage for about a year. These dry serums will make the determination of the M and N factors possible in laboratories that are not equipped for the preparation of the immune agglutinins.

Indications for Removal of Vasoconstrictors in Diseases of Extremities—Rieder had excellent results with ramisectomy combined with sectioning of the sympathetic fibers in allaying the pain and delaying or entirely preventing gangrene in vasomotor disturbances of the extremities. The failures in his material as well as in the reports in the literature are, in his opinion, the result of faulty indication for operative intervention. Elimination of vasoconstriction can be effective only when the underlying condition is essentially on a vasoconstrictor basis. Constriction of the arteries of the skin leads to diminution in the volume of blood circulating in it and to lowering of its temperature. Organic occlusion of an artery can no longer be influenced by sympathectomy. The problem is to estimate before the operation the dilating capacity of the vessels. The question of hyperemia reaction can be tested by anesthetizing the nerves running to the extremity or, still more effectively, by anesthetizing the brachial plexus when studying the upper extremity and by spinal anesthesia for the study of the vessels of the lower extremity. The author's experience with this diagnostic procedure in a large number of cases convinced him of its validity. If the test results in a definite hyperemia and hyperthermia instead of coldness and cyanosis of the limb, the sympathectomy as a rule will be effective. The positive test is followed at once by the operation, since the duration of spinal anesthesia is not less than two hours. Exact measurements of the skin temperature are essential. One could expect no beneficial results from the operation if the rise of temperature was less than one degree. The author made an interesting observation, i. e., that brachial plexus anesthesia of one side sometimes produced hyperemia and

hyperthermia of the opposite side. This corresponds with the clinical observation that unilateral sympathectomy may bring about a temporary improvement in the opposite side. The author does not agree with the opinion that a complete removal of sympathetic fibers paralyzes the vessels. He showed in his microcapillary studies that the capillary reflex remained intact and that it could be elicited by external stimuli. The regulating mechanism remains unaltered, since the autonomic nerve plexuses reside within the blood vessels. The peripheral nerve plexuses are independent to so high a degree that in spite of the removal of the corresponding ganglions and of sympathetic branches combined with a periarterial sympathectomy they continue to regulate the peripheral circulation and to dilate or to constrict the vessels according to the needs of the peripheral circulation. They are autonomic in the fullest sense of the word. The rise of temperature may persist for years. The periarterial sympathectomy alone is incapable of bringing about such results. The author cites several histories with appended skin temperature charts to show that when the anesthesia test resulted in a rise of skin temperature of three or more degrees the operative results were gratifying. To the contrary, no benefit followed the operation when the skin temperature rise was less than one degree.

Treatment of Urinary Incontinence in Women.—Santi states that in 1919 he described a simple method for the restoration of the destroyed urethra. Since this report received little attention and since in the meantime his own experiences, as well as those of other Italian surgeons, have proved that the method produces good permanent results, he calls attention to it once more. He stresses the following as the main aims of his method: (1) narrowing of the urethral tube, (2) the utilization of certain factors that permit the formation of valves, (3) the lengthening of the tube that facilitates the discharge of the urine, and (4) the strong curvature or even double curvature of the newly formed urethra. He forms a new channel in the anterior soft portions of the vulva, and this channel lengthens the original urethra or what is left of it.

Tenderness of Left Supra-Orbital Nerve as Sign of Previous Malaria.—Bereskin states that in the course of forty years of practice he has observed, with few exceptions, tenderness of the left supra orbital nerve in patients who gave a history of malaria. The shorter the period since the last attack, the more pronounced was the tenderness. It was always more pronounced in patients with an enlarged spleen. The test is carried out by exerting a gentle pressure simultaneously on the supra-orbital nerves at the point at which they emerge from the supra-orbital notch. This 'supra-orbital phenomenon' is analogous to the phrenicus phenomenon of pain of the right shoulder in diseases of the gallbladder. It is probably not a neuralgia due to malarial toxemia since it has no periods of exacerbation and since it does not explain the predilection for the left side. The more likely explanation is to be sought in stimuli proceeding from the pathologically altered spleen. The symptom should prove of value in clearing up obscure cases of hepatitis and splenic involvement.

*Investigations Concerning Carbohydrate Tolerance in Carbohydrate Hunger. N I Nissen—p 241
Tuberculosis in Sacro Iliac Articulation. H Thomsen—p 253
Evipan Sodium Anesthesia. J Nordentoft—p 261

Carbohydrate Tolerance in Carbohydrate Hunger.—Nissen's experiments showed that, after a few days without carbohydrate administration or with restricted administration on a diet either low or high in calories, a disturbance appeared in the carbohydrate metabolism. There was a fall in the fasting value. Renewed administration of carbohydrate by oral and intravenous application of dextrose resulted in an abnormally high and prolonged alimentary hyperglycemia and marked glycosuria, a transient difference, as a rule less than normal, was seen in the alimentary sugar content in arterial and venous blood. Oral administration of galactose was followed by a galactosemia, too high and too long continued, accompanied by galactosuria, the course of the assimilation curve was not affected after intravenous injection of galactose. The degree of the disturbance seemed to be independent of the intensity of the acidosis and was more marked on a diet low in calories. It is ascribed to a deficient or delayed glycogen synthesis in the liver and the peripheral tissue, possibly together with disorder in the utilization of the administered carbohydrate.

*Investigations on Basophil Substance in Red Blood Corpuscles and Their Structure by Staining with Yellow Cyaninchromalum. J Stefensen—p 269
Nutrition Anemia in White Rats and Its Treatment with Iron and Copper. E E Fog—p 284

Basophil Substance in Red Blood Corpuscles.—Steffensen stained smears from well and sick persons with yellow cyaninchromalum. The red blood corpuscles were hemolyzed and assumed a peculiar granulated appearance. The method seems to him especially suitable for staining the basophilic substance in the red corpuscles, particularly the stippling, and preferable to staining with borax-methylene blue (Manson) in demonstrating the stipple cells because of greater delicacy. The coagulation products produce the stippling. The yellow cyaninchromalum method most closely resembles supravital staining, with the advantage that it indicates both the quantity and the quality (i.e., the shifting to the left) of the basophil substance. The white blood corpuscles are also especially well stained by the combined yellow cyaninchromalum-Leishman method.

ARTIFICIAL PNEUMOTHORAX IN THE TREATMENT OF LOBAR PNEUMONIA

ALBERT BEHREND, MD
AND
ROSCOE B G COWPER, MD
PHILADELPHIA

In 1921 Friedemann,¹ a German clinician, reported favorably on the treatment of lobar pneumonia by artificial pneumothorax, in a series of seven cases. In the same year David² reported six cases similarly treated with good result. Two years later Schottky³ reported a single case successfully treated. Interest in the procedure waned then, or the preliminary articles received scant attention, for not until 1928 does further literature appear on the subject.

A group of pediatricians then borrowed the idea but used it only in cases of pneumonia characterized by abnormally continued fever showing intrapleural collections or bronchiectasis. They advised against its use in acute pneumonias, mainly because they felt that most children recover from the disease with conservative treatment. Ibrahim and Duken,⁴ Duken,⁵ Jahr and Neumann,⁶ and Klotz⁷ reported seventeen cases of childhood pneumonia with protracted fever in which artificial pneumothorax was used, generally with good result and with only three deaths.

In an excellent article on the subject of the treatment of lobar pneumonia in adults by artificial pneumothorax, Coghlan⁸ reported six cases with one death, which was attributed in part to an error of judgment in the amount of air injected. Coghlan was most impressed by the ability of artificial pneumothorax to precipitate a crisis and the prompt relief of pleuritic pain which followed the separation of the parietal from the visceral pleura by air. After the publication of Coghlan's work Guadarrama,⁹ Li,¹⁰ Anderson,¹¹ and Perlroth and Topercer¹² reported good results with this new form of therapy.

Lately Leopold and Leberman¹³ have written a paper on the effect of artificial pneumothorax on lobar pneumonias experimentally produced in dogs. Of eighteen animals treated, three died. Of eighteen dogs untreated, five survived and thirteen died.

Stimulated by the appearance of the article by Coghlan, we decided to apply it clinically to a series of patients at the Philadelphia General Hospital following the suggestion of Dr William Egbert Robertson and with the approval of our respective chiefs of service.

THEORETICAL ASPECTS

When acute inflammation occurs in a part of the body that is functionally or anatomically movable, experience has taught that the primary treatment of the affected part is rest. We may cite, for example, the splinting of the joint in acute arthritides, the immobilization of the extremities in cellulitis and the strapping of the chest in pleurisy. The object is to supplement by mechanical means the natural demands of the organism for rest.

Lobar pneumonia furnishes an excellent example of acute inflammation in an organ whose function requires almost constant movement. Attempts of the body to limit motion of the lung by decreased expansion and shallow, frequent respirations cannot be too successful. The introduction of air into the pleural cavity by artificial pneumothorax furnishes a mechanical aid that admirably accomplishes the desired result.

But rest is not the only benefit that theoretically derives from the use of artificial pneumothorax. When acutely inflamed pleural surfaces are separated, the pain formerly caused by every respiratory excursion disappears. The patient is able to breathe normally, even deeply, without discomfort. This allows the well lung on the unaffected side to expand to capacity, permitting more complete oxygenation of the blood flowing through it. In consequence, cyanosis is diminished.

Most recent experimental studies indicate that artificial pneumothorax causes a decrease in the amount of blood circulating in the collapsed lung. This is still a controversial point. However, Corper, Simon and Rensch¹⁴ and Corper and Rensch¹⁵ have rather conclusively shown that the blood flow through the collapsed lung is gradually decreased. These observations are corroborated by Dock and Harrison,¹⁶ who found that within a few hours after the initiation of artificial pneumothorax from 52 to 58 per cent of the total blood flow passes through the collapsed lung but that within three days this falls to from 9 to 18 per cent. It follows then, that there will be decreased absorption

from the diseased side and a decrease in the amount of unoxygenated blood appearing in the general circulation

Lymph stasis with diminution of absorption of toxins has long been held largely responsible for the beneficent effect of artificial pneumothorax in pulmonary tuberculosis by Riviere,¹⁷ Warnecke,¹⁸ Mariette,¹⁹

Fig 1—Temperature pulse and respiration in case 1 A injection of 330 cc of air B injection of 250 cc

Gardner²⁰ and others It doubtless functions in a similar manner in lobar pneumonia The importance of this fact cannot be underestimated when it is recalled that almost all deaths from lobar pneumonia are due directly or indirectly to toxemia

SELECTION OF CASES

Patients treated at the Philadelphia General Hospital are almost without exception of the underprivileged class Many come to the wards with a history of alcoholism, exposure or malnutrition, and it is not unusual to see persons with frank lobar pneumonia walk into the receiving ward to apply for admission The mortality in this type of case must of necessity be high From Nov 1, 1933, to Jan 1 1934, there were 107 male patients admitted with lobar pneumonia and subsequently treated with various supportive and non-specific measures Of this number forty-seven, or 43.9 per cent, died During the same period thirty-four women were admitted, with eighteen deaths, or a mortality of 52.9 per cent The combined mortality of men and women was 48.4 per cent The mortality among the patients treated with artificial pneumothorax was 18.1 per cent We are aware that it is impossible to draw conclusions from so small a series of cases, but we do feel that the figures here presented are interesting and highly suggestive

Eleven cases provide the clinical material on which this report is based The eleven cases presented physical signs of unilateral lobar pneumonia involving one or more lobes When the patient's condition permitted, the diagnosis by physical signs was checked by roentgenographic study

No effort was made to select patients who looked as if they might or might not get well with or without benefit of treatment Pneumothorax was induced at various stages of the disease and the first injection of air was given as early as the second day of disease and as late as the eleventh day Results tend to show that the time of induction is not a factor of great importance As in the serum therapy of pneumonia, treatment should be instituted as soon as a diagnosis is definitely established

The age of the subjects ranged from 15 to 54

The blood pressure varied from 94 systolic, 42 diastolic, to 160 systolic, 80 diastolic before compression therapy was started

RESULTS OF TREATMENT

There were two deaths among the eleven patients treated In one of these there was an overwhelming septicemia and toxemia, and death was certainly not caused by the treatment given Indeed, it was the feeling of all who saw this patient that his life was prolonged The second death was attributed to pneumococcal meningitis and occurred on the twenty-first day of the disease While it is hard to believe that pneumothorax precipitated the meningitis, it is also true that it did not prevent that dreaded complication of pneumonia in this instance

Artificial pneumothorax was easily inducible in ten of the eleven cases In the exceptional case three attempts were made to introduce air into the pleural cavity There must of necessity be a small percentage of patients in whom this treatment cannot be utilized because of adhesions caused by previous pleuritis or pneumonia with resultant approximation of parietal and visceral pleurae

Without doubt the most striking result of the treatment was the prompt relief of pain and dyspnea To see patients looking sick as only pneumonia patients can, with anxiety expressed in every feature, with every breath seemingly a torture and every cough a knife thrust—to see these patients immediately following successfully induced pneumothorax breathing with surprised ease and lack of pain is most gratifying, and we have seen it occur repeatedly In some cases the patient went to sleep promptly, and this was often the first protracted sleep enjoyed in from forty-eight to seventy-two hours Of course, the patient still has lobar pneumonia and is acutely ill, but the relief of pain afforded by pneumothorax without resort to opium derivatives with their deleterious side-effects changes the psychologic outlook of the case for physician and patient alike

Only slightly less spectacular than the relief of pain was the fall in temperature that followed pneumothorax In one case alone did the initial dose fail to produce a reduction in the degree of fever The crisis,

Fig 2—Temperature, pulse and respiration in case 2 A injection of 350 cc of air

the term being used in the sense that normal temperature occurred in twenty-four hours or less after pneumothorax, was produced in five cases In four additional cases the temperature came down more or less gradually by lysis, in one case adhesions prevented the introduction of air, and in one case the air introduced, while relieving pain, caused no febrile drop

17 Riviere Clive Pneumothorax and Surgical Treatment of Pulmonary Tuberculosis Oxford University Press 1927
18 Warnecke Beitr z Klin d Tuberk 16 171 1910
19 Mariette E C Am Rev Tuberc 16 220 (Aug) 1927
20 Gardner L Am Rev Tuberc 10 220 1924

Clinically and hematologically it appears that artificial pneumothorax, not invariably but sometimes, can cause a critical drop in temperature. How this occurs can only be surmised. Since we believe that pneumothorax causes diminution of absorption of toxins by lymph stasis, we believe it is possible that the mustering immunologic forces are able to overcome toxins suddenly decreased in amount. The temperature fell to normal and stayed there in the successfully treated cases in from two to five days after the first air was introduced, three days being the average time.

The temperature may rise again after an initial post-pneumothorax drop. This is due to absorption of air, which occurs rapidly in pneumonia as shown by roentgen and clinical signs, allowing reexpansion of the compressed lung. Additional air again causes defervescence. When the first injection causes little drop in temperature, a second fill may bring about the desired result.

Toxicity is greatly diminished within twenty-four hours after the injection of air. Even when the effect of the procedure on the temperature, pulse and respiration is slight, "toxemia," as judged by the appearance of the patient, is reduced.

Cyanosis, when present, is relieved.

Cough is diminished and the amount of sputum becomes almost negligible.

Fig 3—Temperature pulse and respiration in case 3. A injection of 500 cc of air. B injection of 500 cc.

It is difficult to follow the course of the disease by physical signs after pneumothorax because the signs of pneumothorax replace those of pneumonia. With absorption of air and consequent expansion of the lung, the breath sounds again become audible and at this time the affected lung is usually in a stage of late resolution.

None of the commonly anticipated complications occurred in this series. Pyopneumothorax, cardiac collapse, pleural shock, abscess and gangrene of the lung did not develop in a single case. In the patient who died with a septicemia there was also some spread of the pneumonic process to the opposite side. This may constitute a real danger in the use of this form of therapy, but when it is detected the air on the originally affected side can be withdrawn.

Specific serums were not used in conjunction with artificial pneumothorax because these patients were treated in a municipal hospital whose budget for medicines does not at present include antipneumococcic serum. The combination of the two methods in suitable cases may in time come to be recognized as the ideal form of treatment.

TECHNIC OF ARTIFICIAL PNEUMOTHORAX

The usual type of apparatus used in treating patients with pulmonary tuberculosis was employed. The patient is given a drachm (4 cc) of aromatic spirit of

ammonia. He lies flat in bed on the sound side. A small pillow is placed under the ribs. The arm on the affected side is raised to widen the intercostal spaces. The site of injection is prepared with iodine and alcohol. A skin wheal is made with 2 per cent procaine hydrochloride in the seventh-eighth interspace in the posterior axillary line. An 18 or 21 gage needle is

Fig 4—Temperature pulse and respiration in case 4. A injection of 400 cc of air.

attached to a three-way stopcock leading to the pneumothorax machine and a syringe containing procaine hydrochloride. The needle is inserted slowly, infiltrating with procaine hydrochloride down to and through the parietal pleura. That the needle is in the pleural cavity is determined by reading the oscillations of the water column in the manometer of the apparatus. The pressure should be negative and the oscillations were usually quite wide. Air is introduced slowly and manometric readings are made after each 50 cc. If the pressure becomes positive or the patient complains of pain, the needle is immediately withdrawn. From 400 to 500 cc usually produced the desired effect without causing a mediastinal shift. The same amount is then repeated in from eighteen to twenty-four hours. Two injections usually suffice. Injection of air by syringe and needle alone without benefit of a manometer may be likened to a blindfold intravenous puncture and is mentioned only to be heartily condemned.

CONCLUSIONS

1 Eleven patients with unilateral lobar pneumonia were treated with artificial pneumothorax to compress the affected lung, with two deaths. Neither of these fatalities could be directly attributed to the pneumothorax.

2 We believe that collapse therapy is a rational form of treatment of lobar pneumonia, based on sound surgical principles.

3 That lung tissue affected by lobar pneumonia can be compressed by air has been shown clinically, by roentgenograms and at autopsy.

4 Artificial pneumothorax relieves the pain of the pleurisy that frequently accompanies lobar pneumonia.

5 It is possible to induce a critical fall in temperature by artificial pneumothorax.

6 We believe that artificial pneumothorax is neither a "cure-all" nor a "therapia magna sterilisans," but it has shown itself to be a valuable adjunct in the treatment of lobar pneumonia and even, we feel, a life saving measure in some cases.

7 We have seen no complications directly attributable to the procedure.

Fig 5—Temperature pulse and respiration in case 5. A injection of 400 cc of air. B injection of 500 cc.

REPORT OF CASES

CASE 1—C G, a man, aged 41, a Negro, admitted to the service of Dr William Egbert Robertson and Dr Cowper, June 14, 1933, had been well until the day before, when he awoke with pain in the right side of the chest. The patient was well developed, acutely ill and dyspneic. There was limitation of expansion, tubular breathing, friction rub on respiration, crepitant rales, marked increase of whispered pectoriloquy, increased fremitus and percussion dulness over the right lower portion of the chest. The blood pressure was 110 systolic, 64 diastolic. The abdomen was distended with gas. Laboratory tests revealed red blood cells, 3,020,000, white blood cells, 17,400, with polymorphonuclears, 88 per cent, lymphocytes, 10 per cent, monocytes, 1 per cent and eosinophils, 1 per cent. The Kahn test was negative. The blood sugar was 122, the blood urea nitrogen, 70. The sputum was positive for type I pneumonia.

A diagnosis of pneumonia of the right lower lobe was made June 15, the third day of disease. 330 cc of air was introduced into the right pleural cavity in the seventh interspace posteriorly.

TABLE 1—Blood Count in Case 5

White Blood Cells	Eosino- phils	Mono- cytes	Myelo- cytes	Juve- niles	Stab Forms	Seg mented Forms	Pol- ymor- pho nuclears	Lym- pho- cytes	S I *
12/11/33 (before artificial pneumothorax)	16,000	2	10	2	8	60	16	56	2 43
12/12/33 (12 hours after artificial pneumothorax)	10,500	5	0	0	0	75	5	80	15 15
12/13/33	12,600	14	0	0	0	50	18	63	18 27
12/14/33	9,000	13	0	2	2	28	62	25	12

only. It was noted immediately that the physical signs in the affected side were muffled after the introduction of air. The replacement of the physical signs of lobar pneumonia by the signs of pneumothorax were noted in every case in which induction of the pneumothorax was successful. June 16, the patient felt much better and the pain in the right lower part of the chest was alleviated. June 17 45 cc of turbid fluid was withdrawn, culture of which showed no growth and direct

Fig 6 (case 5)—Pneumonia of the left lower lobe. A before artificial pneumothorax. B after artificial pneumothorax.

smear no organisms. At the same time 250 cc of air was introduced. The temperature fell from 103.8 to 100 F following this injection but rose again. In retrospect, it seems that more air would have been beneficial in this case. The temperature gradually fell to normal on the ninth day of disease and further course was without incident.

CASE 2—E W, a man, aged 55, a Negro, admitted to the service of Dr Andrew Callahan and Dr Cowper, Nov 28, 1933, had complained of pain in the right upper portion of the chest and a "bad cold" since November 24. On admission it was seen that the patient was very acutely ill and dyspneic.

Physical examination revealed swelling over the manubrium, tender and slightly fluctuant. In addition there were signs of lobar consolidation over the right upper part of the chest. The blood pressure in the left arm was 110 systolic, 74 diastolic, in the right arm it was 96 systolic, 62 diastolic. A diagnosis of pneumonia of the right middle lobe and aneurysm of the aortic arch and innominate artery was made.

Laboratory examination showed red blood cells, 4,300,000, white blood cells, 7,200, Schilling count, myelocytes, 0, juveniles, 0, stab form 15, segmented forms, 30, total polymorphonuclears, 45. The Kahn test was + + + +, blood sugar, 109, blood urea nitrogen, 17. The sputum was negative for tubercle bacilli and positive for pneumococcus group IV.

Fig 7—Temperature and respiration in case 6. A in jection of 500 cc of air. B in jection of 450 cc.

Roentgenograms made November 28 and December 8 showed consolidation of the right upper lobe and aneurysm of the ascending aorta and innominate artery.

November 29 the right side of the chest was needed. No fluid was obtained and 350 cc of air was introduced. Pain and malaise were relieved almost at once, and the temperature fell to normal within twenty-four hours only to rise again and fall spontaneously to normal the next day. Air

was not given on the occasion of the postpneumothorax rise of temperature because the patient looked and felt so much better. He was discharged subsequently in good condition.

CASE 3—S N, a man, aged 54, a Negro, admitted to the service of Drs Callahan and Cowper, Dec 7, 1933, for four weeks prior had complained of a cold and for four days before admission had noted severe pain in the right shoulder and chest, together with cough and expectoration. On physical examination he was acutely ill with signs of pneumonia of the right upper lobe. The blood pressure was 138 systolic, 84 diastolic.

Laboratory examination December 8, showed white blood cells 17,400, polymorphonuclears, 82, lymphocytes, 16. The sputum was negative for tubercle bacilli on three occasions.

December 13, the eleventh day of disease, the patient was given 500 cc of air in the right side of the chest. The patient felt better thereafter, complained less of pain in the chest and was apparently less toxic. On this day a Schilling count read myelocytes, 0 juveniles, 5 stab forms, 53 segmented forms, 28, polymorphonuclears 83 lymphocytes 15, mononuclears 2.

December 16 the patient felt and looked better but the temperature remained elevated. December 20, since the temperature was still elevated, it was decided to introduce more air and a refill of 500 cc was given seemingly with good result for the temperature fell to normal within twenty-four hours. The next day, however, the patient complained of headache. There was slight muscular rigidity, the pupils were pinpoint and did not react to light, and the patient looked very toxic. Lumbar puncture revealed no increase in pressure, but the spinal fluid was turbid and culture revealed group IV pneumococci. The patient grew steadily worse and died on the twenty-first day of the disease.

Autopsy revealed an acute diffuse purulent meningitis, ulcerative endocarditis of the aortic valves and congestion and early bronchopneumonia of both lower lobes. The right upper lobe, which was the seat of the original lobar pneumonia, was tightly compressed and presented the picture of unresolved pneumonia.

CASE 4—L E, a Negro woman aged 30, admitted to the service of Drs Callahan and Cowper, Dec 15, 1933, said that she had been feeling well until December 10, when she awoke with headache and pain in the left lower part of the chest. She also had some chills and a cough. On physical examination she was acutely ill presenting signs of lobar consolidation over the left upper part of the chest. The blood pressure was 94 systolic 42 diastolic. The abdomen was slightly distended. December 16 a roentgenogram showed a pneumonic consolidation

tion of the left upper lobe Four hundred cubic centimeters of air was introduced into the left side of the chest The temperature did not begin to fall appreciably until the next day, but despite this she felt much better and stated that the chest pain had entirely disappeared Three days after the single injection of air the temperature was normal and remained so, and the patient was discharged in good condition

Laboratory examination of the blood (Schilling) showed white blood cells, 21,900, myelocytes, 0, juveniles, 2, stab forms, 50, segmented forms, 12, polymorphonuclears, 64, lymphocytes, 25, monocytes, 10, eosinophils, 1

Fig 8 (case 7)—Pneumonia of the right middle lobe A, before artificial pneumothorax B right lateral view before artificial pneumothorax C after artificial pneumothorax

Blood culture showed no growth

The sputum was negative for tubercle bacilli and showed pneumococcus group IV

CASE 5—B S, a white youth, aged 15 years, very large for his years, admitted to the service of Dr F J Kalteyer and Dr Behrend, Dec 11, 1933, became ill, December 7, with cough, yellow sputum and pain in the left lower part of the chest On physical examination the patient was acutely ill, with definite signs of consolidation of the left lower lobe A friction rub was present at the left base The blood pressure was 100 systolic, 72 diastolic

TABLE 2—Blood Count in Case 6

7,400		1	7	5	70	10	97	2	87

At 9 p m on the day of admission the left pleura was punctured and 400 cc of air introduced A roentgenogram taken just before had confirmed the diagnosis of pneumonia of the left lower lobe Following the first air injection the patient appeared more comfortable and slept without the aid of narcotics, a fact worthy of note in view of his statement that he had not slept for the two preceding nights because of chest pain Eight hours after pneumothorax the temperature was normal

December 12, the improvement in the condition of the patient was evident to all The pain in the side disappeared and was replaced by an indefinite soreness Despite the improvement, an additional 500 cc of air was introduced and the patient was sent for roentgen study The report by Dr Ostrum at this time read Artificial pneumothorax left side with partial collapse of the left lower lobe (about 33 per cent) There is a small amount of fluid in the sinus There is also a partial collapse of the left upper lobe and the heart is displaced somewhat to the right

December 14 the temperature was normal and the patient felt so well that he asked to be discharged Breath sounds

were already returning on the treated side, attesting to the rapid absorption of air in the presence of acute pulmonary infections This phenomenon was observed in every case in which artificial pneumothorax could be induced and, doubtless, accounts for the rise in temperature frequently seen after a preliminary fall from a single injection of air

Some of our cases, such as case 5, were checked by daily Schilling white blood counts, and thus has furnished us with an interesting commentary on the manner in which artificial pneumothorax acts in lobar pneumonia Dr W G Crocker, who has made a careful study of Schilling counts in the laboratory of the Philadelphia General Hospital, has found that in pneumonia it is impossible to distinguish hematologically between crisis and a prelethal state Schilling counts made during the period of defervescence following artificial pneumothorax show the same confusing picture This would appear to furnish another link in the chain of evidence indicating that pneumothorax may precipitate crisis

Laboratory examination showed blood sugar, 102, blood urea nitrogen, 21 The Kahn test was negative Blood culture yielded no growth The blood count is given in table 1

The patient left the hospital twelve days after admission in good condition and without complications

CASE 6—J W, a man, aged 38, a Negro, admitted to the service of Drs Kalteyer and Behrend, Dec 26, 1933, complained of pain in the right chest and side The onset occurred at 2 a m, December 25, when the patient was awakened from sleep by pain in the chest He felt very ill and had a severe productive cough, but no chill was noted

When seen the patient was apparently very acutely ill He was robust, breathing with difficulty and perspiring freely There were signs of consolidation of the right lower lobe A friction rub so severe that it was easily palpable was present on the right side The blood pressure was 122 systolic, 80 diastolic The rhythm was regular Tympanites was present Shortly after admission, 500 cc of air was introduced into the right pleural cavity Relief from pleuritic pain was noted immediately, and the patient required only one-half grain

Fig 9—Temperature pulse and respiration in case 7 A injection of 50 cc of air B injection of 400 cc C injection of 300 cc

(0.03 Gm) of codeine for sleep that night December 27, the temperature having fallen to normal and risen again, 450 cc of air was introduced Following this he looked comfortable, and apparently improved, sleeping almost the entire day without narcotics Roentgenograms made at this time were reported by Dr Ostrum as showing 33 per cent collapse of the right lung considerable fluid at the right base and consolidation of the right lower lobe During the night he became irrational and continued so throughout the day (December 28), his pulse gradually mounting until death

Laboratory examination showed blood sugar, 160, blood urea nitrogen, 36. Blood culture, December 27, was positive for group IV pneumonia, there were too many colonies to count. The Schilling blood count is given in table 2.

Pneumothorax was still present when the chest was opened at autopsy. The right lung was partially but uniformly com-

pressed. The right lower lobe showed a confluent bronchopneumonia and pleuritic adhesions to the diaphragm. There was 400 cc of fluid containing fibrinous flakes in the right side of the chest. The left lower lobe showed a few areas of patchy bronchopneumonia.

In retrospect, it would appear that this patient, the only one in this series to show a positive blood culture, was doomed no matter what the treatment. The overwhelming septicemia and the lack of febrile and leuko-

cytic response as well as the severe toxicity all boded ill. Yet it cannot be denied that artificial pneumothorax made him look and feel much better until a few hours before death. The pain of a severe pleurisy was relieved and it may be said that if a cure was not effected at least death was made more comfortable.

Fig 10—Temperature pulse and respiration in case 8. A injection of 150 cc of air B, injection of 50 cc C injection of 50 cc

pressed. The right lower lobe showed a confluent bronchopneumonia and pleuritic adhesions to the diaphragm. There was 400 cc of fluid containing fibrinous flakes in the right side of the chest. The left lower lobe showed a few areas of patchy bronchopneumonia.

cytic response as well as the severe toxicity all boded ill. Yet it cannot be denied that artificial pneumothorax made him look and feel much better until a few hours before death. The pain of a severe pleurisy was relieved and it may be said that if a cure was not effected at least death was made more comfortable.

CASE 7—M R, a woman, aged 43, admitted to the service of Drs Kalteyer and Behrend, Dec 26, 1933, complained of pain in the back and neck, cough and chills, which began on the day of admission.

Sputum was blood streaked. She reeked of alcohol on admission and admitted that she drank at least a pint of spirits a day. Physical examination showed only impairment to percussion at the right base and a light friction rub in the posterior axillary line. December 27 there were definite signs of a right middle lobe consolidation and rales were also present over the right lower lobe. A roentgenographic

Fig 11—Temperature pulse and respiration in case 9. A injection of 350 cc of air B, injection of 400 cc

report by Dr Ostrum showed definite evidence of a right middle lobe pneumonia. Artificial pneumothorax was attempted but the patient was very apprehensive and uncooperative. After 50 cc of air had been introduced, the patient complained of pain and the intrathoracic pressure had become positive. The needle was withdrawn. December 28, the patient seemed a little better. Pneumothorax was again attempted and

Fig 12 (case 10)—Right lower lobar pneumonia with pleurisy A before induction of air B after induction of artificial pneumothorax

50 cc of air was injected and the patient complained of pain. The needle was withdrawn. January 2 the experience of the preceding day was repeated, only 50 cc of air was given. Further attempts to induce artificial pneumothorax were abandoned. The patient then went on to a spontaneous crisis on the ninth day of disease.

TABLE 4—Blood Count in Case 10

White Blood Cells	Eosino- phils	Mono- cytes	Myelo- cytes	Juve- niles	Stab Forms	Seg mented Forms	Polymor- pho nuclears	Lym- pho- cytes	S I
1/15/34 10,100		4	3	12	51	24	90	6	35
1/16/34 15,800		8	0	0	62	28	90	2	12
1/17/34 31,800		0	2	2	68	28	100	0	25

This case is included in these records because it illustrates that in lobar pneumonia, as in pulmonary tuberculosis, a preceding or an accompanying pleuritis may render impossible the induction of an artificial pneumothorax.

CASE 9—M S, a woman, aged 29, admitted to the service of Drs T G Schnabel and A S Moscarella, Dec 31, 1933, complained of pain in the right side of the chest, cough and weakness. She had had a "cold" since December 26. On the

day before admission a severe pain had developed in the right side of the chest, cough became more severe, sputum was bloody and there was shortness of breath. Physical examination showed signs of lobar pneumonia over the right upper and middle lobes. The blood pressure was 122 systolic, 72 diastolic. The abdomen was slightly distended.

Fig. 13—Temperature, pulse and respiration in case 10. A injection of 300 cc of air. B injection of 400 cc.

On the day of admission, 350 cc of air was introduced into the right side of the chest. Within ten hours the temperature had fallen to normal and the patient said that she felt much better and that the pain had gone. Jan. 1, 1934, the temperature rose to 103.2 F, although the sputum had become scanty and the patient felt much better. She was given 400 cc of air on the affected side. Fourteen hours later the temperature was normal and remained so until discharge from the hospital. Laboratory examination of the sputum was negative for pneumococci but positive for Friedländer's bacillus. Blood culture was negative.

CASE 10—P. K., a man, aged 29, admitted to the service of Drs. William E. Robertson and V. L. Tuck, Jan. 11, 1934, complained chiefly of pain in the right side of the chest. He had had a severe infection of the upper respiratory tract for a week before admission. January 9 he had had severe pain in the right side of the chest, chills, blood-streaked sputum and a high fever. On physical examination the patient was very acutely ill and toxic. There were signs of consolidation over the right lower lobe and a friction rub in the posterior axillary line. The blood pressure was 110 systolic, 60 diastolic. The pulse was rapid and of poor volume. Rigidity was present in the right upper quadrant.

January 11 roentgenograms showed the presence of right lower lobe pneumonia with pleurisy. Three hundred cubic centimeters of air was introduced into the right pleural cavity. Respiratory pain was immediately relieved. January 12 the temperature had fallen somewhat, the patient was reading a newspaper and laughing and remarked that he "felt fine" and all pleuritic pain had left. Late in the day the temperature rose and 400 cc. of air was given. The temperature fell again.

Fig. 14—Temperature, pulse and respiration in case 11. A injection of 400 cc of air. B injection of 450 cc.

temporarily but rose the next day. No alarm was felt, however, because the patient felt so much better. By January 18 all air had been absorbed but the temperature at that time was normal.

On laboratory examination the Kahn test was negative, blood culture on two occasions showed no growth.

Blood sugar was 98, blood urea nitrogen was 18. The blood count is given in table 4.

CASE 11—J. B., a man, aged 48, a Negro, admitted to the service of Drs. Robertson and Tuck, complained chiefly of fever and pain in the left side. Jan. 15, 1934, the patient had a chill, the temperature rose, the sputum was blood streaked and epistaxis occurred. The pain in the chest was severe.

On physical examination the patient was acutely ill. There were signs of lobar pneumonia over the left upper lobe, and a friction rub was present. The blood pressure was 140 systolic, 70 diastolic.

TABLE 5—Blood Count in Case 11

White Blood Cells	Eo phils	Mono cytes	Neu- tro- cytes	Juve- niles	Stab Forms	Seg- mented Forms	Poly- morpho nuclears	Lym- pho- cytes	S. I.
1/20/34 15,000		16	0	17	25	30	77	0	12
1/22/34 19,000		8	0	0	40	40	80	12	1

January 16, 400 cc of air was introduced into the left pleural cavity. Following this, the patient felt much better and the pain in the chest was relieved. The temperature dropped from 103.4 to 100 F. The procedure was repeated, January 17, and 450 cc of air was given with benefit to the temperature and general well being of the patient.

Roentgenograms taken January 20 showed artificial pneumothorax on the left side with density over the entire left upper lobe.

The Wassermann reaction was 4 plus, blood sugar was 120, blood urea nitrogen was 45. The sputum showed pneumococcus group IV. The blood count is given in table 5.

Thirty-Fourth and Pine streets

TRANSURETHRAL RESECTION OF THE PROSTATE

IMPROVED INSTRUMENTS AND OPERATIVE INDICATIONS

HUGH H. YOUNG, MD
BALTIMORE

Transurethral surgery for the obstructing prostate goes back one hundred years. Among the most important procedures proposed were those of Mercier, ultimately discarded on account of the mechanical imperfections, hemorrhage and infection. Then came the transurethral electrocautery operation of Bottini, improved much later by the instruments of Freudenberger, Young and Chetwood. This operation was used very widely, the question of immediate hemorrhage was solved by the cautery, but extensive sloughing, gangrene, occasional extravasations and even injuries of the rectum, generalized sepsis and, particularly, recurrence of the obstruction months later led to the abandonment of the Bottini operation, which for a time swept prostatectomy off the boards. I did seventy-five Bottini operations in cases of enlarged prostate, but the complications and the mortality drove me again to take up the perineal route, which resulted in the introduction of the conservative perineal prostatectomy by my double bladed tractor. This operation was accompanied by amazingly little mortality. For one period of three and one-half years, 198 consecutive patients (six of whom were over 80 years of age) were operated on without a death.

Then cases appeared of the fibrous type, contractures of the vesical orifice, bars and valves in which the tissue was not enucleable and the attack through the perineum not entirely satisfactory. Some of these cases

From the James Buchanan Brady Urological Institute, Johns Hopkins Hospital.

I attacked suprapubically, with poor results, owing to the inability to remove the intra-urethral bar or contracture just within the vesical orifice. It was then that I brought out my transurethral prostatic excisor, or "punch." By means of the fenestra on the posterior surface, bars, lobes and the like can be entrapped, excised or treated by electrocautery, or fulguration, so

Fig 1—1 Young's punch with a tube attached through which a long needle can be passed and anesthetic injected into the tissue. 2 A syringe attached to a long needle and the tip of the needle emerging near the fenestra. 3 A spear with the tip at an angle to the shaft. It is inserted into the inner cutting tube and plunged into the tissue. As the spear is rotated the tissues to be excised are drawn into the fenestra and held in position. 4 Spear placed in punch with tip turned downward. 5 The spear has been rotated, showing the tip turned upward.

as to stop the bleeding. Encouraged by the simplicity of the operation, I tried this procedure in increasingly larger prostates. In many of these I found difficulty in entrapping the lobe and also in holding the entrapped tissue while it was cut away by the sharp inner tube. To obviate this I used a small electric motor to make the inner tube revolve rapidly, with greater success in cases of hypertrophy, but the instrument was not entirely successful. To combat this deficiency I have recently devised a lance-shaped spear, by means of which the tissue entrapped in the fenestra is speared and drawn farther into the fenestra. A curve has recently been placed on the end of the spear, which allows it to go more deeply into the prostatic tissue to be removed and then, by rotation, draws still larger amounts in the fenestra, as shown in 3, figure 1.

For many years I have generally employed local anesthesia, plus a little preliminary morphine, to carry out transurethral resection with the "punch." Recently I have used a long needle to plunge into the entrapped tissues and thus obtain, by injecting procaine hydrochloride, better anesthesia. Still more recently, Mr. Angele, the chief mechanic of the Brady Urologic Institute, has placed a minute tube on the posterior surface of the outer tube, which carries a needle through which the injections are made (2, fig 1).

THE NEW TECHNIC

Careful cystoscopy is carried out with the cystourethroscope, sometimes with the addition of the simple urethroscope. In this way the obstructing contracture, bars, valves or lobes at the vesical orifice projecting into the bladder or into the urethra, are carefully noted and charted. The size of the trigone, its elevation and its proximity to the median enlargement is carefully charted, so that at operation the trigone may be surely avoided. The thickness of the tissues between the

trigon, prostate and rectum are carefully determined. If my transurethral excisor or "punch" is to be used, it is introduced, and turned first to the right, the obturator is removed and the sheath is drawn outward until the right lateral margin of the prostate is caught in the fenestra. The needle in the outer tube is then plunged into this tissue, and an injection of 5 cc of 1 per cent procaine is made (1, fig 2). Such injections are also made on the opposite side, posteriorly, anteriorly and, if desirable, between these points. In this way the vesical neck is completely infiltrated, and operations may then be carried out with very little pain. In some cases calculi have been present in the bladder. In these I have also infiltrated the base of the bladder by intentionally catching the trigone with the fenestra and injecting it and the posterior surface of the bladder with procaine hydrochloride. Litholapaxy can then be carried out almost painlessly. After this excisions of the prostatic tissue, as indicated by the previous cystoscopy, are done.

THE SPEAR TECHNIC

When it has been decided to make, at first, the right lateral cut the instrument is introduced, the obturator removed, the bladder filled, and the instrument turned to the right and withdrawn quickly to stop escape of fluid. The right lateral margin with its enlargement, is entrapped in the fenestra. The spear is then plunged into the deeper portion of the entrapped mass, the instrument going out of the fenestra obliquely into the prostatic tissue (2, fig 2). A curved rod that impinges

Fig 2—1 Punch turned to right with tissue partly engaged in fenestra. The needle has entered the tissue and anesthetic is being injected. 2 The spear turned outward has been plunged into the tissue. 3 The spear rotated drawing a greater amount of tissue into the fenestra. 4 The inner cutting tube is pushing forward, excising tissue as the end of the spear holds it firmly in position.

on the plate of the punch (4, fig 1), allows the spear to go only the proper distance. In order to draw the prostatic tissue more deeply through the fenestra into the outer sheath of the excisor or punch, it is simply

necessary to rotate the angulated spear 180 degrees. This inevitably draws considerably more tissue into the instrument (3, fig 2), and fixes it while the operator quickly pushes home the cutting tube (4, fig 2). Thus removed the large mass of tissue within the fenestra.

By means of this spear technic the tissue now removed is much greater than that obtained with the old punch, or certain electrical resectors, as shown in figures 3 and 4. The excision on the right side is continued with one or more cuts, perhaps in varying directions as previously shown to be necessary by previous cystoscopic and endoscopic study. One may also attach the endoscopic light, swab the tube clean and thus inspect the remaining tissues and determine whether further excision should be made. The same thing can be done with Caulk's irrigating cystoscope which may be attached to the instrument and used to inspect the vesical neck during or after excisions. Having com-

pleted the work on the right side, the operator usually turns to the left, carries out the same procedure—alternately ensnaring, spearing, drawing into the urethra and pushing the cutting tube quickly inward to excise the entrapped lobe. Here again one or more additional cuts may be made. One then turns to the posterior margin. The cutting tube is withdrawn, partly opening the fenestra; there is a rush of bladder fluid, and the fenestra, directed backward, is then withdrawn until arrested.

The question now arises, "Have I caught the trigon, or passed over it and entrapped the median portion of the prostate?" It is very important to settle this question, because

the division of the trigon either by instruments of the punch type or by electrical resection, has been responsible particularly with the latter for extravasation and rectovesical injury. To determine whether the trigon has been caught in the fenestra one simply turns the instrument 90 degrees to the right (fig 5). This will release the trigon, and if one makes traction the instrument will come outward until caught by the right prostatic margin. It can then be turned backward so as to entrap the median portion. If the middle lobe projects farther into the bladder than the lateral, the operator may find it necessary to go a little farther in to catch it, but by following this technic practically no difficulty is encountered in avoiding the trigon. In some six hundred prostatic resections I have apparently never had a case of trigonal injury.

In rare instances there is a definite bar or lobule anteriorly which requires removal, but the operator must be very cautious not to go too deep. I have seen a case in which several anterior cuts were made that

resulted in prevesical extravasation, requiring suprapubic drainage. Such ought not to occur.

The operator having convinced himself that an abundance of tissue has been removed the question of arresting hemorrhage comes up. I have found the use of fulguration most satisfactory (fig 6). Under

Fig 3—Specimen removed by Young's punch instrument ten pieces weighing 4 Gm

Fig 4—Specimen removed by McCarthy resectoscope thirty-one pieces weighing 5.5 Gm

Fig 5—Manner in which a hypertrophied trigon may be caught in the fenestra of the punch instrument (a and b). By turning the instrument 90 degrees as shown in c and d the fenestra is freed from the trigon and when drawn outward catches at the lateral margin of the prostate.

cystoscopic observation with continuous irrigation, the bleeding points are easily recognized and seared with the electric spark. This may be carried out through the punch instrument, as provided in Caulk's cysto-

scopic attachment, or by the introduction of an ordinary catheterizing cystoscope

At the end of this procedure, there is little or no necrotic tissue left behind, no slough to come away and produce severe secondary hemorrhage, and no necrotic nidus for infection and even gangrene. The simplicity of the procedure is shown by the fact that in

Fig. 6—Arresting hemorrhage by fulgurating bleeding points through catheterizing cystoscope showing the condition after the cuts have been made and hemorrhage being stopped by fulgurating electrode

about 600 cases, excluding two of carcinoma, one also of diabetes mellitus in which the patient died in uremic coma, the mortality has been about 0.5 per cent

If one wishes to do transurethral surgery on a much more enlarged prostate, I would not recommend my instrument. By the electric loop it is possible to go deeper and to continue the removal for hours (as has been done). I saw one case in which the operator produced a huge cavity on the right side, and even gravely injured the external sphincter, but left behind a left lobe 2 inches long on the left side. As the patient described it "the operation took three hours, a handful of little pieces were removed and I found myself incontinent." But such must happen rarely, although it is

Fig. 7—Young's radical operation for carcinoma of the prostate. Removal of the entire prostate cuff of bladder vasa deferentia and seminal vesicles. Anastomosis of the bladder to the membranous urethra

quite possible to do great damage with the unrestrained use of the powerful electric loop. In careful hands, and particularly when the operation is done in two or three stages, much tissue can be removed with comparative safety, although the mortality in a large series of cases has not been. I believe, as low, nor the results as

good, as with the simple or the cautery punch, as shown by Caulk's remarkable series of some 15,000 collected cases

The loud acclaim of the transurethral resection of the prostate has come very largely from those surgeons who have been most addicted to suprapubic prostatectomy. With the passage of time the ultimate mortality of the suprapubic route has been shown to be much too high. The preliminary cystostomy alone has presented a sizable mortality. Keyes has frankly acknowledged a mortality of 40 per cent in his series of suprapubic prostatectomies. He decided that pre-vesical infection, extravasation and extension of suppurative processes behind the abdominal muscles have been the most frequent cause of death. To avoid this he has advised a series of different suprapubic techniques by which the wound may be walled off to prevent the aforesaid complications.

Those who have adhered to the perineal route for the great majority of cases still believe that it is a comparatively safe operation, since it has the advantage that the prostatic operation is under the control of

Fig. 8—Perineal prostatectomy through inverted V capsular incisions. Final stage of enucleation of lateral and median lobes in one piece

the eye, and indurated and suspicious areas may be palpated, incised, excised and examined microscopically for malignancy. If cancer is present, the operation can be so modified as to make it a radical removal, which now has the proud record of over 50 per cent of cured cases followed more than five years (fig. 7).

I need not stress the great advantages of the perineal operation in cases of multiple calculi, which are so frequently found between the hypertrophied lobes and the nonhypertrophied capsule. Through the perineum it is possible to see and avoid the external sphincter, the verumontanum, ejaculatory ducts and the trigon. Sloughing and gangrene almost never occur, hemorrhage is completely arrested, infection is taken care of by excellent drainage, and antiseptics may be freely employed. Perineal prostatectomy can be done in a fraction of the time that is required for the transurethral electrical resections in even moderate hypertrophies. As the hypertrophied lobes are completely enucleated, although the patient may stay in the hospital a little longer, he gets entirely well in a much shorter time and, what is more, he stays well.

In pointing out the great simplicity and multiple advantages of the perineal route, I do not wish to condemn transurethral surgery, as a matter of fact, it is employed in my clinic with great frequency, and there are many cases in which it is distinctly preferable to prostatectomy. Both the electric and the plain cutting instruments are used. With the introduction of improved instruments, the tube for injections of procaine hydrochloride, the rotating, angulated spear to secure larger excised masses, and the accurate fulguration of all bleeding points, much progress has been made. The advantages of the punch operation, with the spear technic, are briefly as follows: the simple convalescence, due to absence of slough, the comparative avoidance of infection and secondary hemorrhage, the quicker healing, and the greater freedom from suppuration and pain.

In the more advanced cases of prostatic hypertrophy my punch, even with the spear, is not satisfactory. For such cases perineal prostatectomy is greatly to be preferred to any transurethral operation, even though it is possible to remove much tissue by the punch and by electroresection. The clean enucleation of hypertrophied lobes through the perineum (fig. 8) is certainly more permanently curable and is accompanied by less suppuration and grave complications than after electroresection.

Prostatic surgery has now arrived at a point where it is one of the safest major operations. By means of transurethral surgery and accurate visual perineal prostatectomy, the high mortality of the past should be completely eliminated and many more cases of carcinoma recognized early and cured.

RAT-BITE FEVER ACQUIRED FROM A DOG

HERBERT S. RIPLEY, M.D.
AND
HELEN M. VAN SANT
CHICAGO

Rat-bite fever, or sodoku, from the Japanese *so* (rat) and *doku* (poison), has been recognized as a clinical entity in India for many centuries. Row¹ quotes a description of the disease by Wagabhata, an ancient Indian who lived 2,300 years ago. Early modern reports of cases were made by Wilcox² and by Watson³ in 1840. Miyake⁴ described the symptomatology in detail in 1899. Excellent reviews have appeared recently, notably those of Robertson,⁵ who gives a summary of the etiologic aspects of the disease and appends a good bibliography, McDermott,⁶ who studied the biologic characteristics of the organism, and Bayne-Jones,⁷ who reviewed the cases reported in the United States.

Rat-bite fever is widely distributed over the world. Perhaps the disease is more common than is generally recognized. Many people die after the bite of a rat without a definite diagnosis. Neel⁸ reports that, after the clinical entity had been called to the attention of the local medical profession, five cases were diagnosed in one county in South Carolina during 1929.

SYMPTOMATOLOGY

The history of a bite by a rat is usually given. Cases caused by bites or scratches of other animals have been reported. The wound heals cleanly unless there is secondary infection. The incubation period commonly is from one to four weeks. With the onset of systemic manifestations there is pain, swelling, redness and vesicle formation. In some cases an ulcer develops in the center of the primary lesion, with a serous discharge from which the causative agent has been isolated. Pus is not present unless there is a mixed infection with organisms such as streptococci, staphylococci or streptothrix, all of which have been recovered from the regional lymph nodes in typical cases. Lymphangitis and local and generalized lymphadenopathy occur.

Chills, fever, rapid pulse, prostration, anorexia, generalized aching of the muscles, headache, stupor and delirium commonly characterize the onset. After a few days there is a remission, followed by regular or irregular paroxysms of fever with intervals of from three to eight days between attacks. As the disease progresses, each subsequent attack tends to be less severe than the preceding one. There is considerable variation in the type of temperature curve, as shown in figure 1. The chart of case 1 is more typical of the average course than that of case 2. During remissions, all symptoms except weakness usually disappear.

Early in the disease, nodules resembling those of erythema nodosum and measuring from 0.5 to 5 cm. in diameter are present. At first they are bright red and moderately indurated and they blanch on heavy pressure. Soon they develop a purplish hue and the induration disappears. Finally there is a brownish discoloration and a fine flaking desquamation, which may last several weeks. A diffuse erythema with an irregular margin frequently is present with the febrile attacks. The blood shows a slight to severe anemia and a leukocytosis most marked during rises in temperature.

PROGNOSIS

The mortality in untreated cases in Japan is reported as 10.5 per cent by Miyake. With the advent of arsphenamine therapy, deaths have been rare. Most fatal cases occur during the first severe febrile attack, but some follow later from nephritis or other complications. The possibility of double infection by Streptothrix or other micro-organisms must be remembered. If response to arsenic is not prompt, such a complication is likely.

TREATMENT

Arsphenamine therapy, which was introduced by Hata⁹ in 1912, is specific. Since recurrences are common when less than three injections are given, a course of from three to six injections seems advisable.

ETIOLOGY

Since Futaki and his collaborators¹⁰ in 1916 discovered in Japan the spiral organism which they named

Spirochaeta morsus-muris and described as the causative agent of rat-bite fever, their work has been confirmed by several others in various parts of the world. Though the classification of the organism as a spirochete or a spirillum is still more or less under discussion, the organism found in cases in different parts of the world seems to be identical with the one discovered by the Japanese workers and the name *Spirillum morsus-muris* (or *Spirillum minus*) has been rather generally accepted. A review of the literature and an excellent bibliography dealing with the etiology of the disease and the nomenclature of the organism are given by Robertson.⁶

In the review of rat-bite fever in the United States by Bayne-Jones, a report is made of seventy-five cases which he considered genuine rat-bite fever, in five of which *Spirillum morsus-muris* was recovered. The streptothrix reported by Schottmuller,¹¹ Blake,¹² Dick and Tunnichiff,¹³ and others and the sporothrix reported by Anderson and Spector¹⁴ probably were secondary invaders.

REPORT OF CASES

CASE 1—C. A., a man, aged 26, married, a second year medical student entered the University of Chicago Clinics,

Fig. 1 (case 1)—Temperature chart. Each line represents the range in temperature for one day.

Aug. 24, 1933, complaining of a sore on the finger of the right hand. August 17, while he was performing an operation on a dog, a ligature slipped and cut the skin on the right fifth finger at the distal interphalangeal joint. This cut healed in two days. On the third day the site of the lesion became red and painful, but these symptoms subsided when hot soaks were applied, only to flare up again on the following day, when they were again relieved by heat. On the fifth day the lesion became red, swollen and tender, and no relief was obtained from hot soaks. On the seventh day he came to the clinic. An incision was made and no pus was obtained. The tissue was found to be tough and similar to cartilage in its resistance to the knife. The patient was sent to the hospital.

On physical examination the positive manifestations were a painful, swollen, tender, inflamed right fifth finger with an incision along the medial aspect and a palpable, tender lymph node in the right axilla.

The white blood cells numbered 6900, the red blood cells, 5,200,000 with hemoglobin, 80 per cent. The urine was normal.

From August 24 to October 10 the patient had an intermittent fever with rises and falls at irregular intervals. From October 10 to November 3 the fever was definitely relapsing in type with sharp rises every five days (fig. 1). Accompanying the elevations in temperature were chills, prostration, generalized aches and pains, leukocytosis reaching as high as

33,200, anorexia, headache, erythema on the chest and abdomen, nosebleeds, frequent irrationality and mental depression. Although the patient was weak, he felt remarkably well between attacks of fever.

August 30 there appeared numerous firm, inflamed tender areas 2 cm in diameter extending from the right fifth finger to 5 inches above the elbow. Similar lesions later appeared on the back, chest and legs. These lesions were more inflamed during the febrile periods. After October 1 they faded gradually and left a brownish discoloration of the skin, which was almost imperceptible at the time of discharge from the hospital.

His weight fell from 160 to 109 pounds (72.6 to 49.4 Kg). The primary lesion on the right fifth finger remained inflamed for months and was not completely healed until November 4. An acute episcleritis developed in both eyes. On several occasions he had nausea and vomiting and nosebleeds during relapses. Lymphadenopathy became generalized. There was slight enlargement of the epididymides.

November 3, two days after the laboratory examination had confirmed the diagnosis of rat-bite fever, solution arsenical compound No. 16 (Lilly),¹⁵ 0.3 Gm. which contains 0.009 Gm. of arsenic, was given intravenously. Four hours after the injection, nausea and vomiting developed, followed by weakness and a rise of temperature to 104°. The following day he had no symptoms. November 5 and 7, 0.45 and 0.5 Gm., respectively, of the same drug were given without untoward effect. November 11 he was discharged from the hospital, feeling

weak but otherwise in good general condition.

CASE 2—F. H., a man, aged 22, single, a second year medical student, entered the University of Chicago Clinics, Oct. 14, 1933, complaining of fever, malaise and muscle soreness.

During August he had worked on the same animals as patient 1 in the physiology laboratory. About August 24 there developed a red, swollen, firm sore on the distal phalanx of the left thumb. No abrasion of the skin at this time or previously was noted.

Moist hot applications were administered for several days. Since no marked change occurred, the lesion was incised and a small amount of blood tinged serum, but no pus, was expressed. Healing was prompt after incision.

During the last week of August he drove from Chicago to his home in San Diego, Calif. The long journey left him completely exhausted. After five days in bed he felt well for several days. About September 1, soreness developed in the muscles of his arms and legs. Four nodules about 2 cm in diameter which soon became red and tender, appeared on the extensor surface of the left forearm. At first there was no discoloration of the skin. Later there was a brownish color, which disappeared slowly. He had night sweats, chills, fever and weakness which kept him in bed for three weeks. The temperature is said to have remained below 102° F.

The first week in October he came back to medical school. At this time he felt well. Several days after his return he had a recurrence of the malaise and fever. During the first two weeks of October his temperature was between 100 and 102° F, which was usually higher in the afternoon. There was soreness in the muscles of the extremities, slight stiffness of the neck, a tired feeling in the arms without exercise, and red, slightly itchy lesions on the back of the thorax. His weight had fallen from 160 to 140 pounds (72.6 to 63.5 Kg).

The only unusual observations at physical examination were a palpable spleen felt about 1 cm below the costal margin, a faint blowing systolic murmur in the pulmonic area, muscle tenderness of the arms and legs and a small nodule at the head of the left epididymis.

¹⁵ This is a temporary name for this product and will be used until a permanent name has been adopted.

¹⁴ Anderson N. P. and Spector Bertha K. Rat Bite Fever As associated with Sporothrix. J. Infect. Dis. 50: 344-349 (April) 1932.

The white blood cells numbered 9,050, the red blood cells 3,670,000, with hemoglobin 67 per cent (Sahl). The urine was normal. Blood smear showed normal cells and no parasites. The differential count was polymorphonuclear neutrophils, 84 per cent, lymphocytes, 13 per cent, monocytes, 2 per cent, eosinophils, 1 per cent.

The temperature course is shown in figure 2. With each rise in temperature there was an increase in the white blood cells up to as high as 23,600, diffuse mottled macular erythema on the chest, generalized muscle soreness and stiffness that

were most marked in the legs, loss of appetite, slight conjunctivitis, sweating, twitching of small groups of muscles and flushing of the face. On two occasions small, firm red papules, which developed pustular centers and were followed by persistent brownish discoloration of the skin, were noted on the back of the thorax. Although malaise was never severe the patient felt much better between attacks.

Fig. 2 (case 2)—Temperature chart. Each line represents the range in temperature for one day.

Under iron therapy (45 Gm pills of ferrous carbonate) the hemoglobin rose from 67 per cent to 82 per cent (Sahl).

Following the injection of 0.45 Gm of neoarsphenamine on November 3, the temperature rose from 100 to 105.5 F within six hours. There was profuse sweating, drowsiness, a feeling of lightness in the head, and vague substernal discomfort. Two additional injections of 0.5 and 0.6 Gm of neoarsphenamine were given on successive days without reactions.

LABORATORY OBSERVATIONS

Several agglutination tests for tularemia and undulant fever were negative in both cases and repeated blood cultures on various culture mediums showed no growth. Stool and urine cultures were essentially negative and wound cultures in case 1 showed *Staphylococcus aureus* or *albus*, nonhemolytic streptococci or no growth.

The serum in case 1 gave a positive Weil-Felix agglutination 1:320 repeatedly with X19 while that in case 2 was positive only 1:40 X19. The serum of both patients gave positive agglutinations with *Bacillus typhosus* and *B. paratyphosus* A and B. Both had had TAB vaccine.

The Wassermann and Kahn tests gave interesting results in both cases as shown in table 1. Because of the strongly positive Kahn tests a spirochetal disease was suspected. This led to animal inoculations which gave positive results, confirming the diagnosis of rat-bite fever (table 1).

ANIMAL INOCULATIONS

Animal inoculations were made with blood of the patients as follows:

Case 1. September 22, two guinea-pigs received 4 cc each of venous blood intraperitoneally. October 20, three guinea-pigs received 4 cc each of venous blood intraperitoneally, three mice received 1 cc each of venous blood intraperitoneally and one dog received 5 cc of venous blood into the femoral vein.

Case 2. October 18, two mice received 1 cc each of venous blood intraperitoneally. October 19, three more mice were inoculated in the same manner. In addition, three guinea-pigs and one dog were inoculated as in case 1.

RESULT OF ANIMAL INOCULATIONS

Mice—All mice inoculated with blood from each patient showed *Spirillum morsus-muris* in the peripheral blood by dark field and stained smear. They appeared on the eleventh day after inoculation in one case and on the thirteenth day in the other. The mice for the most part, remained apparently healthy except for occasional loss of hair and conjunctivitis. The spirilla have been carried on in mice to the fifth series and have been found in the peripheral blood on the seventh day after inoculation from mouse to mouse.

Guinea-Pigs—All guinea-pigs succumbed to the disease within two months after inoculation. Spirilla were never demonstrated in the peripheral blood or any, though search was made repeatedly after the eighth day. The animals remained apparently well until a few days before death, when they suddenly became weak and emaciated. They usually showed conjunctivitis and keratitis and, occasionally, loss of hair. Temperatures showed a slight elevation.

Little was noted grossly on autopsy with the exception of catarrhal enteritis. Smears from various organs showed no spirilla. Spirilla were found only in smears of discharge from the eyes and then in only three cases.

The Wassermann and Kahn tests done on two guinea-pigs a few days before death were negative.

Mice inoculated with heart blood from three of these guinea-pigs showed no spirilla, though examination was made at intervals for thirty-seven days.

Dogs—The dog in case 1, which received 5 cc of blood in the femoral vein on October 20, had a temperature between 102 and 104 for thirty-three days. On the thirty-third day the animal was found dead.

On the fourteenth day after he was inoculated, mice were injected with blood from this dog and after about two months spirilla were found in their peripheral blood. A guinea-pig inoculated November 15 with blood from the dog developed the typical disease and died after one month. Spirilla were found in smears of the discharge from the eyes. The Wassermann and Kahn reactions on this dog, November 13, were both negative.

TABLE 1—Results of Kolmer, Wassermann and Kahn Tests

Case 1	9/9	Wassermann negative	Kahn negative
	10/24	Wassermann negative	Kahn 2-3-2
	10/25	Wassermann negative	Kahn 1-2-1
	11/3	Specific therapy	
	11/7	Wassermann negative	Kahn 4-4-4
	11/13	Wassermann weakly positive 1-1	Kahn 4-4-4
Case 2	11/20	Wassermann negative	Kahn 4-4-4
	10/17	Wassermann anticomplementary	Kahn 4-4-4
	10/23	Wassermann weakly positive 0-1	Kahn 1-4-4
	10/27	Wassermann weakly positive 0-1	Kahn 4-4-4
	11/3	Specific therapy	
	11/7	Wassermann negative	Kahn 4-4-4
	11/13	Wassermann weakly positive 0-1	Kahn 4-4-4
	11/16	Wassermann negative	Kahn 4-4-4
	11/20	Wassermann negative	Kahn 4-4-4
	1/3/24	Wassermann negative	Kahn 3-3-1
	1/23/24	Wassermann negative	Kahn 3-3-1

At autopsy the dog showed ulcers in the colon and purulent pneumonia. Other organs were grossly normal. A search for spirilla in various organs, namely, the spleen, lymph nodes, liver, lung and kidney, by dark field and stained smears, gave negative results.

The dog inoculated on October 19 with blood from case 2 showed similar changes in the temperature and pulse. Mice inoculated with blood from this dog December 1, were positive for spirilla after eighteen days.

The results of the Wassermann and Kahn tests are given in table 2

December 22, treatment was begun on this dog. His weight was 4 Kg. He received 0.3 Gm of solution arsenical compound No. 16 (Lilly)¹⁵ intravenously. Jan. 2, 1934, his temperature dropped to normal.

TABLE 2—Results of the Wassermann and Kahn Tests

11/13	Wassermann negative	Kahn negative
12/1	Wassermann anticomplementary	Kahn strongly positive 4-4-4
12/22	Wassermann weakly positive 1-1	Kahn strongly positive 4-4-4
1/18	Wassermann strongly positive 4-4	Kahn positive 3-4-4

January 18 he received 0.5 Gm of No. 16 intravenously in the right leg and has since shown no symptoms.

It is interesting to note in this connection that Mooser¹⁶ was able to demonstrate spirilla in the blood of a dog and cat after inoculation, while we obtained,

Fig. 3—*Spirillum morsus muris* in blood of inoculated mice

on several occasions, negative results with both dark field examination and stained blood smears on dogs.

THERAPEUTIC INOCULATION

A patient with dementia paralytica, on whom arsenic, bismuth compounds, diathermy and typhoid therapy had been ineffective was inoculated intravenously with 0.75 cc of blood from a mouse infected with blood from patient 1. After twelve days, swelling, redness and tenderness appeared at the site of injection and developed into a bluish gray area with puckering of the skin. No spirilla were found in smears from vesicles at the margin of the lesion or in mice inoculated with this patient's blood. However, a guinea-pig inoculated intracutaneously developed a typical local lesion and succumbed to the disease. The patient developed characteristic clinical rat-bite fever with muscle soreness, chills, red nodules and a temperature curve similar to that in case 1 with variations between 99.5 and 104 F.

Six weeks after inoculation the disease was terminated by means of the arsenical used in case 1. Rat-bite fever therapy for dementia paralytica was first used by Solomon¹⁷ in 1926.

DISCUSSION OF LABORATORY OBSERVATIONS

There are three interesting points in the laboratory observations in these cases: (1) the fact that the Kahn tests were consistently positive and the Kolmer Wassermann tests occasionally positive, (2) the failure to demonstrate spirilla in the peripheral blood of guinea-pigs and (3) the fact that dogs were experimentally infected.

There is considerable variation in the Wassermann reactions in cases reported in the literature. Arkin¹⁸ reports a negative Wassermann reaction in his own case and states that Kitagawa and Mukoyama report a negative reaction and Kunusaki found one positive case in five. Costa and Trouser,¹⁹ Mauriac,²⁰ Caldwell and Templeton²¹ and Briggs²² have reported cases with positive Wassermann reactions. Ward²³ found a case with a four plus Wassermann reaction when cholesterinized antigen was used and a negative reaction with other antigens. Bayne-Jones found fifteen cases with negative and three with positive Wassermann reactions in eighteen American case reports and felt that there was a possibility of a coincident syphilis in the positive cases. Blum and Clement²⁴ state that they found reports of fourteen cases with positive and twelve with negative Wassermann reactions. They cite a case with a negative reaction before and a positive one after rat-bite fever infection. McDermott mentions that he obtained a positive Sachs-Georgi test on inactivated blood of an infected rat, while the Wassermann and the Sachs-Georgi test on infected guinea-pigs were negative. Bayne-Jones also states that he never found a positive Wassermann reaction to occur with the blood serum of experimentally infected guinea-pigs.

The two guinea-pigs that we tested gave negative Wassermann reactions, while the dog that survived gave first a positive Kahn and later a positive Kolmer Wassermann as well.

The failure to find spirilla in the peripheral blood of guinea-pigs is not unlike experiences encountered by other workers. McDermott states that differences have been described in the infections in guinea-pigs produced by various strains of human origin. Mooser²⁵ describes latent infection in guinea-pigs in which no clinical signs of illness developed. Frequent examination of their blood gave only negative results, though spirilla were harbored in their lymph nodes.

Futaki and his collaborators²⁶ state that mice are the best experimental animals, especially when human
